On binary coproducts of frames

XIANGDONG CHEN

Abstract. The structure of binary coproducts in the category of frames is analyzed, and the results are then applied widely in the study of compactness, local compactness (continuous frames), separatedness, pushouts and closed frame homomorphisms.

Keywords: frame, binary coproduct, pushout, compactness, separatedness, continuous frame, closed homomorphism, D(κ)-frame

Classification: 06A15, 18A20, 18A30, 54C10, 54D10, 54D30, 54D45

Coproducts in the category of frames are usually viewed as counterparts of products in the category of topological spaces. The discrepancy between them has produced well-known remarkable properties of frames, for instance, the localic Tychonoff Theorem is constructively valid, and paracompactness is preserved under coproducts of frames. It is certainly worthwhile to study in particular the simplest type of coproducts — binary coproducts.

Let π be the nucleus, defined on the downset-frame of \( L_1 \times L_2 \), determining the coproduct \( L_1 \oplus L_2 \). When dealing with \( L_1 \oplus L_2 \), we often meet the following problem: Given a downset \( U \) of \( L_1 \times L_2 \) and \( (a, b) \in \pi(U) \), what are the internal relations between \( (a, b) \) and \( U \)? Through the analysis of the (pre)nuclei and their combinations involved in constructing binary coproducts, we obtain a useful result, Proposition 2.2, which is a generalization of the technique introduced by Banaschewski [1] and Vermeulen [13] to show that strongly Hausdorff compact frame is regular, from which we gain substantial insight. The great power of Proposition 2.2 is then illustrated by its wide applications in the study of frame counterparts of classical topological facts related to (local)compactness, Hausdorff space and closed continuous maps. All discussions, except the last part of Section 4, are constructively valid.

1. Preliminaries.

For general facts concerning frames we refer to Johnstone [10].

Let \( L \) be a frame. The top (bottom) element of \( L \) will be denoted by \( e \) (0). For any subset \( A \subseteq L \), let \( \downarrow A = \{ x \in L \mid x \leq a \ \text{for some} \ a \in A \} \). For \( a \in L \), its pseudocomplement is denoted by \( a^* \). For a frame homomorphism \( h : L \rightarrow M \), its right adjoint is denoted by \( h^r : M \rightarrow L \) and is given by \( h^r(b) = \bigvee \{ x \in L \mid h(x) \leq b \} \). A frame homomorphism \( h : L \rightarrow M \) is called dense if \( h(x) = 0 \) implies \( x = 0 \); it is called codense if \( h(x) = e \) implies \( x = e \).

This article is part of a Ph.D. thesis written under Professor B. Banaschewski at McMaster University. I am grateful for his invaluable guidance and suggestions.
A frame $L$ is called regular if $a = \bigvee \{x \in L \mid x < a\}$ for each $a \in L$, where $x < a$ means $x^* \lor a = e$.

Given $a, b \in L$, we say $a \ll b$ (way below) if $b \leq \bigvee S$ for some $S \subseteq L$ implies that $a \leq \bigvee E$ for some finite subset $E$ of $S$. A frame $L$ is called continuous if $a = \bigvee \{x \in L \mid x \ll a\}$ for each $a \in L$. In a continuous frame, the $\ll$-relation interpolates, that is, $a \ll b$ implies there exists a $c$ with $a \ll c \ll b$.

Concerning the construction of coproducts in the category $\mathbf{Frm}$, we adopt the approach introduced by Banaschewski [1], [4] as follows.

Recall that a nucleus on a frame $L$ is a closure operator on $L$ which preserves binary meets. A prenucleus on $L$ is a map $k_0 : L \longrightarrow L$ such that, for all $x, y \in L$: (1) $x \leq k_0(x)$, (2) if $x \leq y$ then $k_0(x) \leq k_0(y)$, (3) $k_0(x) \lor y \leq k_0(x \lor y)$. For each prenucleus $k_0$ on $L$, there is a unique nucleus $k$ which has the same fixed points as $k_0$ and is given by $k(x) = \bigwedge \{t \mid x \leq t, t \in K\}$. We will call $k$ as the associated nucleus of $k_0$.

Consider a family $(L_i)_{i \in I}$ of frames with a decidable index set $I$. Let $L \subseteq \prod L_i$ consist of all those $a = (a_i)_{i \in I}$ whose support $\text{spt}(a) = \{i \in I \mid a_i < e_i\}$, $e_i$ the unit of $L_i$, is finite. Then $L$ is a sublattice of $\prod L_i$. The maps $k_i : L_i \longrightarrow L$ defined by

$$k_i(x)_j = \begin{cases} x & (j = i) \\
 e_j & (j \neq i) \end{cases}$$

preserve arbitrary joins and arbitrary meets.

Let $\mathcal{D}$ be the frame of all down-sets in $L$, and define $\pi_0 : \mathcal{D} \longrightarrow \mathcal{D}$ by

$$\pi_0(U) = \{a \land k_i(\bigvee T) \mid a \in L, i \in I, T \subseteq L_i, a \land k_i(t) \in U \text{ for all } t \in T\}.$$ 

Then $\pi_0$ is a prenucleus on $\mathcal{D}$, and we use $\pi$ to denote the associated nucleus.

**Proposition 1.1.** Fix $(\pi_0)$ is the coproduct of $(L_i)_{i \in I}$ in $\mathbf{Frm}$, with coproduct maps $q_i = \pi \circ \downarrow \circ k_i : L_i \longrightarrow \text{Fix}(\pi_0)$.

Furthermore, Banaschewski [4] introduced prenuclei $\sigma_0$ and $\mu_0$ on $\mathcal{D}$, which are defined respectively by, for any $U \in \mathcal{D}$,

$$\sigma_0(U) = \{\bigvee D \mid \text{updirected } D \subseteq U\},$$

and

$$\mu_0(U) = \{a \land k_i(\bigvee T) \mid a \in L, i \in I, \text{ finite } T \subseteq L_i, a \land k_i(t) \in U \text{ for all } t \in T\}.$$ 

Let $\sigma$ and $\mu$ denote the associated nuclei. One of the benefits of having $\sigma_0$ and $\mu_0$ is shown by

**Proposition 1.2.** $\pi = \sigma \circ \mu$.
2. Binary coproducts.

For binary coproducts, we have a more detailed description of the above general construction. Consider two frames $L_1$ and $L_2$ and let $p_i : L_1 \times L_2 \to L_i \ (i = 1, 2)$ be the projection maps.

Let $\pi_1, \hat{\pi}_1, \pi_2, \hat{\pi}_2 : \mathcal{D} \to \mathcal{D}$ be defined by

\[
\pi_1(U) = \{ (\bigvee X, y) \mid X \times \{y\} \subseteq U \}, \\
\hat{\pi}_1(U) = \{ (\bigvee X, y) \mid X \text{ is finite and } X \times \{y\} \subseteq U \}, \\
\pi_2(U) = \{ (x, \bigvee Y) \mid \{x\} \times Y \subseteq U \}, \\
\hat{\pi}_2(U) = \{ (x, \bigvee Y) \mid Y \text{ is finite and } \{x\} \times Y \subseteq U \}.
\]

**Lemma 2.1.** Let $i, j \in \{1, 2\}$.

1. For any $U \in \mathcal{D}$, $U \subseteq \hat{\pi}_i(U) \subseteq \pi_i(U) \subseteq \pi(U)$.
2. $\hat{\pi}_i$ and $\pi_i$ are nuclei on $\mathcal{D}$.
3. $\hat{\pi}_i \circ \pi_j \circ \hat{\pi}_i = \pi_j \circ \hat{\pi}_i$ for $i \neq j$.
4. $\hat{\pi}_i \circ \pi_j \circ \hat{\pi}_i = \pi_j \circ \hat{\pi}_i$ for $i \neq j$.
5. $\hat{\pi}_1 \circ \hat{\pi}_2 = \hat{\pi}_2 \circ \hat{\pi}_1$.

**Proof:** We only provide proofs for (2) and (3), other parts are obvious.

(2) We show that $\pi_1$ is a nucleus. Obviously, $\pi_1$ preserves the partial order. To prove that $\pi_1$ is idempotent, we consider $U \in \mathcal{D}$ and $Z \times \{y\} \subseteq \pi_1(U)$. For each $z \in Z$, take $X_z = \{ x \in L_1 \mid (x, y) \in U \text{ and } x \leq z \}$, which satisfies $X_z \times \{y\} = \left( ((\downarrow z) \times \{y\}) \cap U \right.$ and $z = \bigvee X_z$. Then,

\[
\bigvee Z = \bigvee \bigcup_{z \in Z} X_z, \quad \text{and} \quad \left( \bigcup_{z \in Z} X_z \right) \times \{y\} \subseteq U,
\]

hence $(\bigvee Z, y) \in \pi_1(U)$. It follows that $\pi_1 \circ \pi_1(U) = \pi_1(U)$, therefore $\pi_1$ is idempotent. Finally, if $(x, y) \in \pi_1(U) \cap V$ for some $U, V \in \mathcal{D}$ then $x = \bigvee X$ and $X \times \{y\} \subseteq U$ with some $X \subseteq L_1$. One has also $X \times \{y\} \subseteq V$ since $V$ is a downset, hence $(x, y) \in \pi_1(U \cap V)$. This shows that $\pi_1(U) \cap V \subseteq \pi_1(U \cap V)$, hence $\pi_1$ preserves binary meets.

(3) To see $\hat{\pi}_2 \circ \pi_1 \circ \hat{\pi}_2 = \pi_1 \circ \hat{\pi}_2$, it suffices to show that $\pi_1(U)$ is fixed by $\hat{\pi}_2$ whenever $U$ is fixed by $\hat{\pi}_2$. Suppose $U$ is fixed by $\hat{\pi}_2$. Then $(e, 0) \in U \subseteq \pi_1(U)$. Further, for any $(x, y_1), (x, y_2) \in \pi_1(U)$, take $A, B \subseteq L_1$ such that $x = \bigvee A = \bigvee B$, $A \times \{y_1\} \subseteq U$ and $B \times \{y_2\} \subseteq U$, then $(a \land b, y_1 \lor y_2) \in U$ for any $a \in A, b \in B$, which implies $(x, y_1 \lor y_2) = (\bigvee \{a \land b \mid a \in A, b \in B\}, y_1 \lor y_2) \in \pi_1(U)$. Hence $\pi_1(U)$ is fixed by $\hat{\pi}_2$. \qed

Now, we have three nuclei: $\mu = \hat{\pi}_1 \circ \hat{\pi}_2 = \hat{\pi}_2 \circ \hat{\pi}_1$, $\pi_2 \circ \hat{\pi}_1$, $\pi_1 \circ \hat{\pi}_2$. Combining with Proposition 1.2, it follows easily that
Proposition 2.1. $\pi = \sigma \circ \mu = \sigma \circ \pi_2 \circ \hat{\pi}_1 = \sigma \circ \pi_1 \circ \hat{\pi}_2$.

Since there are explicit expressions for $\mu$, $\pi_2 \circ \hat{\pi}_1$ and $\pi_1 \circ \hat{\pi}_2$, the main problem in analyzing the values of $\pi$ arises how to deal with $\sigma$. Recalling the nature of $\sigma_0$ (defined via updirected sets), we expect that certain conditions of compactness will be helpful.

For a frame $L$, $a \in L$ is called $i$-compact if, for any $b \in L$, $a \ll b$ implies $a \ll c \ll b$ for some $c \in L$. It is easy to see that any compact element is $i$-compact; and in a continuous frame $L$, $a \ll b$ implies that $a$ is $i$-compact by the interpolation property of $\ll$. The purpose for this new concept is to unite the study of compact elements, on the one hand, and the relation $\ll$ in a continuous frame, on the other.

Lemma 2.2. Let $U \in \mathcal{D}$. If $(a, b) \in \pi(U)$, $c$ is $i$-compact and $c \ll a$, then $(c, b) \in \pi_2 \circ \hat{\pi}_1(U)$.

Proof: Let $S = \pi_2 \circ \hat{\pi}_1(U)$. In the interval $[S, \pi(S)]$ in $\mathcal{D}$, let $W = \{V \in [S, \pi(S)] : (a, b) \in V \text{ and } c \ll a \text{ implies } (c, b) \in S\}$.

1. $W$ is $\sigma_0$-stable: Take $V \in W$. Consider any $(a, b) \in \sigma_0(V)$ and $c \ll a$. Suppose $(a, b) = \sqrt{D}$ for updirected $D \subseteq V$. We can find $m$ such that $c \ll m \ll a$, and get $(x_0, y_0) \in D$ such that $m \leq x_0$. For any $(x, y) \in D$ with $(x, y) \geq (x_0, y_0)$, by $c \ll m \leq x_0 \leq x$ we get $(c, y) \in S$. Since $b = \bigvee \{(x, y) \in D : (x, y) \geq (x_0, y_0)\}$, we get $(c, b) \in S$. Hence $\sigma_0(V) \subseteq W$.

2. It is trivial that $S, W = \bigcup W \in W$. Hence $\sigma(W) = W$, and $\sigma(S) \subseteq W$, which implies $\sigma(S) \subseteq W$.

Finally, by Proposition 2.1, $\pi(U) = \sigma(S) \subseteq W$. □

Applying this, we immediately get a key result as follows.

Proposition 2.2. Consider $U \in \mathcal{D}$.

1. If $a \in L_1$ is compact and $a \oplus b \leq \pi(U)$, then $(a, b) \in \pi_2 \circ \hat{\pi}_1(U)$.
2. If $L_1$ is continuous, $a \oplus b \leq \pi(U)$ and $c \ll a$, then $(c, b) \in \pi_2 \circ \hat{\pi}_1(U)$.
3. If $a \in L_1$ is an atom and $a \oplus b \leq \pi(U)$, then $(a, b) \in \pi_2(U)$.

For the convenience of further study, we make the following general observation on the values of $\pi_1$ and $\pi_2 \circ \hat{\pi}_1$.

Lemma 2.3. For any $A \subseteq L_1 \times L_2$, $\pi_1(\uparrow A) = \uparrow \{(\sqrt{p_1[K]}, \bigwedge p_2[K]) : K \in A\}$.

Proof: Suppose $(x, y) \in \pi_1(\uparrow A)$. Then there is a $Z \subseteq L_1$ such that $Z \times \{y\} \subseteq \uparrow A$ and $x = \sqrt{Z}$. Put $K = \{(a, b) \in A : (z, y) \leq (a, b) \text{ for some } z \in Z\}$.

Then $(x, y) = (\sqrt{Z}, y) \leq (\sqrt{p_1[K]}, \bigwedge p_2[K])$.

The other inclusion is trivial. □
Lemma 2.4. For any \( A \subseteq L_1 \times L_2 \), \((x, y) \in \pi_2 \circ \widehat{\pi}_1(\downarrow A)\) if and only if
\[
y \leq \bigvee \{ \bigwedge p_2[K] \mid \text{finite } K \subseteq A \text{ and } \bigvee p_1[K] \geq x \}.
\]

**Proof:** Let \( U = \downarrow A \). We have \( \widehat{\pi}_1(U) = \downarrow \{ (\bigvee p_1[K], \bigwedge p_2[K]) \mid \text{finite } K \subseteq A \} \). \((x, y) \in \pi_2(\widehat{\pi}_1(U))\) means that there exists a subset \( Y \subseteq L_2 \) such that \( \{x\} \times Y \subseteq \widehat{\pi}_1(U) \) and \( \bigvee Y = y \). However, \( \{x\} \times Y \subseteq \widehat{\pi}_1(U) \) is equivalent to
\[
Y \subseteq \downarrow \{ \bigwedge p_2[K] \mid \text{finite } K \subseteq A \text{ and } \bigvee p_1[K] \geq x \}.
\]
Therefore, \((x, y) \in \pi_2 \circ \widehat{\pi}_1(U)\) if and only if
\[
y = \bigvee Y \leq \bigvee \{ \bigwedge p_2[K] \mid \text{finite } K \subseteq A \text{ and } \bigvee p_1[K] \geq x \}.
\]

Due to Proposition 2.2 and Lemma 2.4, the following result becomes apparent. Kříž and Pultr [11] proved it in a different way, employing the Axiom of Choice.

**Proposition 2.3.** Suppose \( L \) is compact and \( M \) is an arbitrary frame. If
\[
e_{L \oplus M} = \bigvee \{ a \oplus b \mid (a, b) \in A \} \quad \text{for some } A \subseteq L \times M,
\]
then
\[
e = \bigvee \{ \bigwedge p_2[K] \mid K \subseteq A \text{ is finite and } \bigvee p_1[K] = e \}.
\]

Sometimes, it is convenient to use the one-one correspondence between elements of \( L_1 \oplus L_2 \) and Galois connections between \( L_1 \) and \( L_2 \). Recall that a pair \([g, g']\) of mappings \( g : L_1 \rightarrow L_2, g' : L_2 \rightarrow L_1\) is a Galois connection between \( L_1 \) and \( L_2 \) if (i) \( g, g' \) are antitone; (ii) \( g' \circ g \geq id_{L_1} \) and \( g \circ g' \geq id_{L_2} \). Given an element \( T \in L_1 \oplus L_2 \), let \( g_T : L_1 \rightarrow L_2 \) be defined by \( g_T(x) = \bigvee \{ y \in L_2 \mid (x, y) \in T \} \), and \( g'_T : L_2 \rightarrow L_1 \) defined by \( g'_T(y) = \bigvee \{ x \in L_1 \mid (x, y) \in T \} \), then \([g_T, g'_T]\) is a Galois connection between \( L_1 \) and \( L_2 \). Conversely, for a Galois connection \([g, g']\) between \( L_1 \) and \( L_2 \), we make \( T_{[g, g']} = \{ (x, y) \mid g(x) \geq y \} \), which is a downset and closed under \( \pi_1 \) and \( \pi_2 \), hence \( T_{[g, g']} \in L_1 \oplus L_2 \). In particular, for the pseudocomplement operator \(*\) of \( L \), the Galois connection \(*, *\) between \( L \) and itself corresponds to the element \( S = \{ (x, y) \in L \times L \mid x \land y = 0 \} \) of \( L \oplus L \).

In the following context, regarding the Galois connection \([g_T, g'_T]\) determined by some \( T \in L_1 \oplus L_2 \), we shall simply write \( x^T \) to denote \( g_T(x) \) and also \( y^{T'} \) for \( g'_T(y) \). Hence
\[
(\bigvee X)^T = \bigwedge \{ x^T \mid x \in X \} \text{ for any } X \subseteq L_1, \text{ or any } X \subseteq L_2.
\]
As an immediate application of above facts, we show that
**Proposition 2.4.** Consider frames $L_1$, $L_2$ and the coproduct maps $q_i : L_i \to L_1 \oplus L_2$ $(i = 1, 2)$. For any $a \in L_1$ and $T \in L_1 \oplus L_2$, we have

$$q_2^r(q_1(a) \lor T) = \bigvee\{b \in L_2 \mid e = a \lor b^T\}$$

if one of the following conditions is satisfied:

1. $L_2$ is continuous.
2. $L_1$ is compact.
3. $a \lor \bigwedge X = \bigwedge\{a \lor x \mid x \in X\}$ holds for any $X \subseteq L_1$.

**Proof:** For any $b \in L_2$ with $e = a \lor b^T$, $(a, b) \in q_1(a)$ and $(b^T, b) \in T$ imply $(e, b) \in q_1(a) \lor T$, it follows that

$$q_2^r(q_1(a) \lor T) \geq \bigvee\{b \in L_2 \mid e = a \lor b^T\}.$$

On the other hand, put

$$U = q_1(a) \cup T,$$

then $\pi_1(U) = \{(x, y) \mid x \leq a \lor y^T\}$, which is fixed by $\hat{\pi}_2$.

Let $c = q_2^r(q_1(a) \lor T)$, then $(e, c) \in q_1(a) \lor T$.

1. Assume $L_2$ is continuous. For any $b \ll c$, $(e, c) \in \pi(U)$ implies $(e, b) \in \pi_1(U)$ by Proposition 2.2, which means $e = a \lor b^T$. Thus

$$c \leq \bigvee\{b \in L_2 \mid e = a \lor b^T\}.$$

2. Suppose $L_1$ is compact. Acting $\pi_2$ on $\pi_1(U)$, we get

$$\pi_2(\pi_1(U)) = \{(x, z) \mid z \leq \bigvee\{y \mid x \leq a \lor y^T\}\}.$$

By Proposition 2.2, $(e, c) \in \pi_2(\pi_1(U))$, which means

$$c \leq \bigvee\{y \in L_2 \mid e = a \lor y^T\}.$$

3. If $a \lor \bigwedge X = \bigwedge\{a \lor x \mid x \in X\}$ holds for any $X \subseteq L_1$, then $\pi_1(U)$ is also fixed by $\pi_2$. It follows that

$$\pi_1(U) = q_1(a) \lor T,$$

hence $c$ satisfies $e = a \lor c^T$.

Therefore, in each of the three cases,

$$q_2^r(q_1(a) \lor T) = \bigvee\{b \in L_2 \mid e = a \lor b^T\}.$$
3. Separated frames.

Consider a frame $L$ and its coproduct maps $q_1, q_2 : L \rightarrow L \oplus L$. The codiagonal map $\nabla : L \oplus L \rightarrow L$, given by $x \oplus y \mapsto x \wedge y$, is the coequalizer of $q_1, q_2$. As usual, $\nabla$ has a dense factorization: $\nabla : L \oplus L \xrightarrow{(\cdot)} \mathcal{S} \rightarrow L$, where $s = \bigvee \{ a \oplus b \mid a, b \in L, a \wedge b = 0 \}$, called the separator of $L$.

We shall call a frame $L$ separated if the codiagonal map $\nabla$ is closed, that is, $\nabla \cong (\cdot) \vee s$ for $s = \bigvee \{ a \oplus b \mid a, b \in L, a \wedge b = 0 \}$ (such $L$ is also called strongly Hausdorff by Isbell [9]).

**Proposition 3.1.** The following are equivalent for any frame $L$:

1. $L$ is separated.
2. In $L \oplus L$, $(c \oplus a) \vee s = (a \oplus e) \vee s$ for all $a \in L$, where $s$ is the separator of $L$.
3. For any $h_1, h_2 : L \rightarrow M$, $(\cdot) \vee t : M \rightarrow \mathcal{S}$ is the coequalizer, where $t = \bigvee \{ h_1(a) \wedge h_2(b) \mid a, b \in L, a \wedge b = 0 \}$.
4. For any $h_1, h_2 : L \rightarrow M$, $h_1(a) \vee t = h_2(a) \vee t$ for all $a \in L$.

**Remark.** In general, even if a pair of homomorphisms $h_1, h_2 : L \rightarrow M$ has its coequalizer of the form $(\cdot) \vee t$ for some $t \in M$, this does not guarantee that $t = \bigvee \{ h_1(a) \wedge h_2(b) \mid a, b \in L, a \wedge b = 0 \}$, as it is shown by the following example: Take $L = 3 = \{0, 1, 2\}$ and $M =$ the Boolean algebra of 4 elements $\{0, a, a', e\}$. Let $h_1 : L \rightarrow M$ be defined by $(0 \mapsto 0, 1 \mapsto a, 2 \mapsto e)$, $h_2 : L \rightarrow M$ be defined by $(0 \mapsto 0, 1 \mapsto a', 2 \mapsto e)$. The coequalizer of $h_1, h_2$ is $(\cdot) \vee e : M \rightarrow \{e\}$ but $\bigvee \{ h_1(a) \wedge h_2(b) \mid a, b \in L, a \wedge b = 0 \} = 0$.

From Isbell [9], we know that regularity is strictly stronger than separatedness. In the following, we shall see that the separatedness is a well behaved property.

The next result was first proved constructively by Vermeulen [13].

**Proposition 3.2.**

1. Compact separated frames are regular.
2. Continuous separated frames are regular.

**Proof:** Apply Proposition 2.4 in the case $L = L_1 = L_2$ and $T = \{(x, y) \mid x, y \in L, x \wedge y = 0\}$, the separator of $L$.

If $a \in L$ with $q_1(a) \vee T = q_2(a) \vee T$, then $a \leq q_2^r(q_1(a) \vee T)$, and it follows that $a \leq \bigvee \{ b \in L \mid e = a \vee b^* \} = \bigvee \{ b \in L \mid b \prec a \}$ if $L$ is compact, or continuous. When $L$ is separated, every element of $L$ has the property of $a$ just assumed. Therefore every compact (or, continuous) separated frame is regular. \qed

**Proposition 3.3.** A frame $L$ is a Boolean algebra if and only if it is separated and satisfies the law: $x \vee \bigwedge S = \bigwedge \{ x \vee s \mid s \in S \}$ for any $S \subseteq L$.

**Proof:** Only the “ if ” part needs proof.

In the proof of Proposition 2.4, we have seen that

$$a \vee c^T = e \text{ if } c = q_2^r(q_1(a) \vee T).$$

Consider $T = \{(x, y) \mid x, y \in L, x \wedge y = 0\}$. If $L$ is separated, which gives $a \leq c = q_2^r(q_1(a) \vee T)$ for all $a \in L$, therefore $a \vee a^* = e$ for all $a \in L$. \qed
Proposition 3.4. Suppose we have a pushout square in Frm:

\[
\begin{array}{ccc}
L & \xrightarrow{v} & M \\
\downarrow{u} & & \downarrow{\bar{u}} \\
N & \xrightarrow{\bar{v}} & P
\end{array}
\]

with separated L. Then:

1. If M is compact, then \(\bar{v}\) is dense whenever \(v\) is codense.
2. If N is compact, then \(\bar{v}\) is codense whenever \(v\) is codense.
3. If N is continuous, then \(\bar{v}\) is monic whenever \(v\) is codense.

Proof: Considering the standard construction of pushouts, we can get the pushout square as follows:

\[
\begin{array}{ccc}
L & \xrightarrow{v} & M \\
\downarrow{u} & & \downarrow{\bar{u}} \\
N \oplus M & \xrightarrow{\bar{v}} & P
\end{array}
\]

where \(q_1, q_2\) are the coproduct injections, \(p = (.) \lor s : N \oplus M \rightarrow s\) is the coequalizer of \(q_1 \circ u, q_2 \circ v\), and \(s = \bigvee\{u(a) \oplus v(b) \mid a \land b = 0\} = \bigvee\{u(a) \oplus v(a^*) \mid a \in L\}\).

Put \(A = \{(u(a), v(a^*)) \mid a \in L\}\), thus \(s = \pi(\downarrow A)\) and \(\downarrow A\) is fixed by \(\mu\).

1. Consider any \(x \in N\) such that \(\bar{v}(x) = 0\). Then \(x \oplus e \leq s = \pi(\downarrow A)\), hence \((x, e) \in \pi_1(\downarrow A)\) by the compactness of M and Proposition 2.2. Now there exists some \(K \subseteq A\) such that

\[
x \leq \bigvee p_1[K] \text{ and } e = \bigwedge p_2[K].
\]

For each \((u(a), v(a^*)) \in K\), \(v(a^*) = e\) implies \(a^* = e\) since \(v\) is codense, hence \(a = 0\). Therefore \(x = 0\). This proves \(\bar{v}\) is dense.

2. Suppose \(\bar{v}(x) = (x \oplus e) \lor s = e_{N \oplus M}\), that is,

\[
(x \oplus e) \lor (\bigvee\{u(a) \oplus v(a^*) \mid a \in L\}) = e_{N \oplus M}.
\]

By Proposition 2.3, we get \(\bigvee\{v(a^*) \mid x \lor u(a) = e\} = e\) in M. Hence \(\bigvee\{a^* \mid x \lor u(a) = e\} = e\) in L since \(v\) is codense, which implies \(\bigvee\{u(a^*) \mid x \lor u(a) = e\} = e\) in N. But \(x = x \lor u(a \land a^*) = (x \lor u(a)) \land (x \lor u(a^*)) = x \lor u(a^*)\), which implies \(x \geq u(a^*)\), and therefore \(x = e\). Hence \(\bar{v}\) is codense, as claimed.
(3) Suppose \( \bar{v}(x) = \bar{v}(y) \). For any \( z \leq x \), from \( x \oplus e \leq (y \oplus e) \lor \pi(\downarrow A) \) and Proposition 2.2, we get \((z, e) \in \pi_2 \circ \hat{\pi}_1(\downarrow (y, e) \cup \downarrow A)\). Then, by Lemma 2.4,

\[
e = \bigvee \{ \bigwedge p_2[K] | \bigvee p_1[K] \geq z \text{ for some finite } K \subseteq \{(y, e) \cup A \}\}
\leq \bigvee \{ v(a^*) | y \lor u(a) \geq z \},
\]

implying \( e = \bigvee \{ a^* | y \lor u(a) \geq z \} \) since \( v \) is codense, hence \( e = \bigvee \{ u(a^*) | y \lor u(a) \geq z \} \), which implies \( z \leq y \). This shows \( x \leq y \), hence \( x = y \) by symmetry. \( \square \)

**Corollary.** If \( L \) is separated and \( N \) is spatial, then the pushout along every \( u : L \rightarrow N \) preserves monomorphisms.

**Proof:** From Proposition 3.4, we know that pushouts along every \( u : L \rightarrow 2 \) preserve monomorphisms, which leads to the claimed fact. \( \square \)

Moreover, Proposition 3.4 provides a constructive proof of the following:

**Proposition 3.5.** Pushouts preserve monomorphisms in the category \( K\text{RegFrm} \) of compact regular frames and also in the category \( \text{RegConFrm} \) of regular continuous frames and frame homomorphisms.

### 4. Closed frame homomorphisms.

**Definition 4.1.** A frame homomorphism \( h : L \rightarrow M \) is called closed if

\[
h^r(h(x) \lor y) = x \lor h^r(y) \text{ for any } x \in L, y \in M.
\]

Among various properties of closed homomorphisms, we only present those involving binary coproducts.

**Proposition 4.1.** For frames \( L_1 \) and \( L_2 \), the coproduct injection \( q_2 : L_2 \rightarrow L_1 \oplus L_2 \) is closed when one of the following conditions is satisfied:

1. \( L_1 \) is compact.
2. \( L_2 \) satisfies the law \( x \lor \bigwedge S = \bigwedge \{ x \lor s | s \in S \} \) for any \( S \subseteq L_2 \).

**Proof:** That \( q_2 : L_2 \rightarrow L_1 \oplus L_2 \) is closed means, for any \( T \in L_1 \oplus L_2, a \in L_2, \)

\[
q_2^r(q_2(a) \lor T) = a \lor q_2^r(T).
\]

Because \( q_2^r(T) = e^T \) for the unit \( e \in L_1 \), the equality (1) holds if and only if \((e, y) \in q_2(a) \lor T\) implies \( y \leq a \lor e^T \).

To analyze (1), it is natural to start with

\[ U = q_2(a) \cup T. \]

We have \( \pi_2(U) = \{(x, y) | y \leq a \lor x^T \} \), which is a downset fixed by \( \mu \).

Obviously, \((e, y) \in \pi_2(U)\) if and only if \( y \leq a \lor e^T \). Therefore, (1) holds if and only if

\[
(2) \quad (e, y) \in \pi(U) \text{ implies } (e, y) \in \pi_2(U).
\]
(1) By Proposition 2.2, \((e, y) \in \pi(U) = \pi(\pi_2(U))\) implies \((e, y) \in \pi_2(U)\) since \(L_1\) is compact.

(2) Now \(\pi(U) = \pi_2(U)\).

Furthermore, as a counterpart of Kuratowski-Mrówka theorem of general topology, the following fact has been obtained by Pultr and Tozzi [12]. By applying the results of binary coproducts developed in this paper, we can present a constructive proof.

**Proposition 4.2** (Pultr and Tozzi). The frame \(M\) is compact if and only if \(q_2: L \rightarrow M \oplus L\) is closed for any frame \(L\).

**Proof:** One direction is actually Proposition 4.1(1). Another direction can be shown by the following modification of the corresponding proof in [12].

Suppose \(U\) is an updirected cover of \(M\). Take \(M\) as an underlying set and define

\[
\mathcal{O}(M) = \{S \subseteq M \mid e \in S \text{ implies } \Uparrow u \subseteq S \text{ for some } u \in U\},
\]

then \(\mathcal{O}(M)\) is a topology on \(M\).

Let \(L = \mathcal{O}(M)\), \(q_2 : L \rightarrow M \oplus L\) is closed means that

\[
q_2^r((e \oplus a) \vee A) = a \vee q_2^r(A) \text{ for any } a \in L, A \in M \oplus L.
\]

Now consider \(a = M - \{e\}\) and \(A = \bigvee \{u \oplus \Uparrow u \mid u \in U\}\).

\[
(e \oplus a) \vee A = \bigvee \{u \oplus a \mid u \in U\} \vee \bigvee \{u \oplus \Uparrow u \mid u \in U\}
\]

\[
= \bigvee \{u \oplus (a \cup \Uparrow u) \mid u \in U\}
\]

\[
= \bigvee \{u \oplus e_L \mid u \in U\}
\]

\[
= e_{M \oplus L}.
\]

Hence \(a \vee q_2^r(A) = e_L\) since \(q_2\) is closed, which implies \(e \in q_2^r(A)\). Therefore there exists an element \(v \in U\) such that \(\Uparrow v \subseteq q_2^r(A)\), that is

\[
e \oplus \Uparrow v \leq \bigvee \{u \oplus \Uparrow u \mid u \in U\}.
\]

By taking the meet with \(e \oplus \Uparrow v\) on both sides, we obtain

\[
e \oplus \{v\} \leq \bigvee \{u \oplus [u, v] \mid u \in U\}.
\]

where \([u, v] = \{x \in M \mid u \leq x \leq v\}\). Notice that \([x, v] \in \mathcal{O}(M)\) for any \(x \in M\).

Put \(W = \{\bigvee K \mid K \subseteq U\}\) and \(S = \{\{w, [w, v]\} \mid w \in W\}\). Then \(S\) is fixed by \(\pi_1\) and \(e \oplus \{v\} \leq \pi(S)\). Since \(\{v\} \in L\) is an atom, by Proposition 2.2, \((e, \{v\}) \in S\), which means \(e = w\), and \(\{v\} \subseteq [w, v]\), for some \(w \in W\), therefore \(v\) must be \(e\). □

The following result is more general than Proposition 4.1(1).
Proof: We need to show, for any frame $T$, $(h \oplus id_N)(T) \subseteq T \cup (h \oplus id_N)(S)$.

We assume $T = \sqrt{\{a \oplus b \mid (a, b) \in A\}$ for some $A \subseteq L \times N$ and $S = \sqrt{\{u \oplus v \mid (u, v) \in B\}$ for some $B \subseteq M \times N$ such that $p_1[A]$ and $p_1[B]$ are updirected. Then $(h \oplus id_N)(T) = \sqrt{\{h(a) \oplus b \mid (a, b) \in A\}$.

Consider any $x \oplus y \leq (h \oplus id_N)((h \oplus id_N)(T) \cup S)$ with $x \in B$.

Then $h(x) \oplus y \leq (h \oplus id_N)(T) \cup S$. By the compactness of $h(x)$, Proposition 2.2 and Lemma 2.4, we have

$$y \leq \sqrt{\{b \wedge v \mid h(a) \vee u \geq h(x) \text{ with } (a, b) \in A \text{ and } (u, v) \in B\}$$

$$= \sqrt{\{b \wedge v \mid a \vee h^r(u) \geq x \text{ with } (a, b) \in A \text{ and } (u, v) \in B\},}$$

which implies

$$x \oplus y \leq \sqrt{\{a \oplus b \mid (a, b) \in A\} \cup \sqrt{\{h^r(u) \oplus v \mid (u, v) \in B\} \leq T \cup (h \oplus id_N)(S)}. \square$$

Remark. Recall that a continuous mapping $f : X \rightarrow Y$ is called perfect if the map $f \times id_Z : X \times Z \rightarrow Y \times Z$ is closed for every space $Z$. We know that $f : X \rightarrow Y$ is perfect if and only if $f$ is closed and the fibre $f^{-1}(y)$ is compact for each $y \in Y$. To some extent, the above proposition can be regarded as a frame counterpart of this topological fact.

For any homomorphism $h : L \rightarrow M$, there exists uniquely an onto homomorphism $G(h) : L \oplus M \rightarrow M$ such that $G(h) \circ q_1 = h$ and $G(h) \circ q_2 = id_M$. $G(h)$ is given by $x \oplus y \leadsto h(x) \wedge y$ and is the coequalizer of

$$q_1 : L \rightarrow L \oplus M \text{ and } q_2 \circ h : L \rightarrow M \rightarrow L \oplus M.$$ 

Consider the factorization $h : L \xrightarrow{q_1} L \oplus M \xrightarrow{G(h)} M$. If $L$ is separated, then $G(h)$ is closed by Proposition 3.1. If $M$ is compact, then $q_1$ is closed by Proposition 4.1. Therefore, we have proved

Proposition 4.4. For separated $L$ and compact $M$, any frame homomorphism $h : L \rightarrow M$ is closed.

Finally, let us allow the Axiom of Choice, so we can talk about cardinalities.
Let $\kappa$ be a regular cardinal. A frame $L$ is called a $D(\kappa)$-frame if it satisfies the following law:

$$D(\kappa): \quad a \lor \bigwedge S = \bigwedge \{a \lor s \mid s \in S\} \text{ for } |S| < \kappa.$$

In the definitions for compact elements and updirected sets, replacing “a finite subset” by “a subset with cardinality strictly smaller than $\kappa$”, we get the definitions for $\kappa$-compact elements and $\kappa$-updirected sets.

Now we continue the observation launched by Proposition 4.1.

**Proposition 4.5.** The coproduct map $q_2 : L_2 \longrightarrow L_1 \oplus L_2$ is closed if one of the following holds:

1. $L_1$ is $\kappa$-compact and regular, $L_2$ is a $D(\kappa)$-frame.
2. $L_1$ has a basis $B$ with $|B| < \kappa$, $L_2$ is a $D(\kappa)$-frame.

**Proof:** Continue to consider the implication (2) in the proof of Proposition 4.1.

(1) Suppose $X \times \{y\} \subseteq \pi_2(U)$ for some $X \subseteq L_1$ with $|X| < \kappa$. Then $y \leq a \lor x^T$ for each $x \in X$, which implies $y \leq \bigwedge \{a \lor x^T \mid x \in X\} = a \lor \bigwedge \{x^T \mid x \in X\} = a \lor (\bigvee X)^T$ since $L_2$ satisfies the law of $D(\kappa)$. It follows that $(\bigvee X, y) \in \pi_2(U)$. It turns out

$$\pi_1(\pi_2(U)) = \{(\bigvee D, y) \mid \kappa \text{ is updirected } D \text{ and } D \times \{y\} \subseteq \pi_2(U)\}.$$

We claim that $\pi_1(\pi_2(U))$ is also fixed by $\pi_2$: Consider $\{x\} \times Y \subseteq \pi_1(\pi_2(U))$. For each $y \in Y$, suppose $x = \bigvee D_y$ with $D_y \times \{y\} \subseteq \pi_2(U)$. Then

$$\left( \bigwedge_{y \in Y} d_y, \bigvee Y \right) \in \pi_2(U) \text{ for } d = (d_y)_{y \in Y} \in \prod_{y \in Y} D_y,$$

so

$$\left( \bigvee_{d} \bigwedge_{y \in Y} d_y, \bigvee Y \right) \in \pi_1(\pi_2(U)).$$

Now,

$$x = \bigwedge_{y \in Y} \bigvee D_y = \bigvee_{d} \bigwedge_{y \in Y} d_y$$

since the $\kappa$-compact regular frame $L_1$ must satisfy this distributive law. Therefore $(x, \bigvee Y) \in \pi_1(\pi_2(U))$, as expected. This shows $\pi(U) = \pi_1(\pi_2(U))$.

Thus, when $(e, y) \in \pi(U)$, there is a $\kappa$-updirected $D$ such that $e \leq \bigvee D$ and $(d, y) \in \pi_2(U)$ for $d \in D$. That $e$ is $\kappa$-compact implies $e \in D$, hence $(e, y) \in \pi_2(U)$.

(2) Consider any $X \subseteq L_1$ and $y \in L_2$ satisfying $X \times \{y\} \subseteq \pi_2(U)$. Take $B_1 = \{b \in B \mid b \leq x \text{ for some } x \in X\}$, then $\bigvee B_1 = \bigvee X$. We have

$$y \leq \bigwedge \{a \lor b^T \mid b \in B_1\} = a \lor (\bigvee B_1)^T = a \lor (\bigvee X)^T,$$

which means $(\bigvee X, y) \in \pi_2(U)$. Therefore $\pi(U) = \pi_2(U)$. \qed
5. Homomorphisms from separated to continuous frames.

Lemma 5.1. Let $L$ be separated and $M$ continuous. If $h : L \to M$ is dense onto, then the set $\{ x \in L \mid h(x) = e \}$ has a least element.

Proof: Put $m = \bigvee \{ h^\ast(c) \mid c \ll e \text{ in } M \}$.

First, $h(m) = \bigvee \{ h h^\ast(c) \mid c \ll e \} = \bigvee \{ c \mid c \ll e \} = e$.

Second, since $M$ is regular continuous, $c \ll e$ means that $\ll c^\ast$ is compact. The composite $L \to M \to \ll c^\ast$ is closed by Proposition 4.4, hence $h^\ast(h(a) \lor c^\ast) = a \lor h^\ast(c^\ast)$ for any $a \in L$. Consider any $x \in L$ with $h(x) = e$. We get $e = h^\ast(h(x) \lor c^\ast) = x \lor h^\ast(c^\ast)$, thus $h^\ast(c) = (x \land h^\ast(c)) \lor (h^\ast(c^\ast) \land h^\ast(c)) = x \land h^\ast(c)$, that is $h^\ast(c) \leq x$. This shows $m \leq x$. Therefore $m$ is the required least element.

\qed

Lemma 5.2. Let $L$ be separated and $M$ continuous. If $h : L \to M$ is dense, codense and onto, then $h$ is an isomorphism.

Proof: Let $k = \text{id}_L \oplus h : L \oplus L \to L \oplus M$, and $s = \bigvee \{ x \oplus y \mid x \land y = 0 \}$ in $L \oplus L$.

Then, since $L$ is separated, for $a, b \in L$,

\[ a \oplus e \leq (e \oplus a) \lor s, \quad \text{and} \quad e \oplus b \leq (b \oplus e) \lor s \text{ in } L \oplus L. \]

Now, suppose $h(a) = h(b)$.

Acting $k$ on the above two inequalities, we obtain

\[ a \oplus e \leq (e \oplus h(a)) \lor k(s) = (e \oplus h(b)) \lor k(s) \leq (b \oplus e) \lor k(s). \]

Since $h$ is dense onto, $h(x^\ast) = h(x)^\ast$ for any $x \in L$. Thus $h(y) = z$ implies $y^\ast \leq h^\ast(z^\ast)$. Therefore

\[ a \oplus e \leq \bigvee \{ x \oplus h(y) \mid x \leq b \text{ or } x \land y = 0 \} \]
\[ \leq \bigvee \{ x \oplus h(y) \mid x \leq b \lor y^\ast \} \]
\[ \leq \bigvee \{ x \oplus z \mid x \leq b \lor h^\ast(z^\ast) \}. \]

Let

\[ T = \{ (x, z) \mid x \leq b \lor h^\ast(z^\ast) \}, \]

which is closed under $\pi_1$ and $\hat{\pi}_2$. By Proposition 2.2, $(a, e) \in \pi(T)$ and $c \ll e$ imply $(a, c) \in T$, that is $a \leq b \lor h^\ast(c^\ast)$, then $h^\ast(c) \land a \leq b$. Thus $\bigvee \{ h^\ast(c) \mid c \ll e \} \land a \leq b$.

On the other hand, $h(\bigvee \{ h^\ast(c) \mid c \ll e \}) = \bigvee \{ c \mid c \ll e \} = e$, which implies $\bigvee \{ h^\ast(c) \mid c \ll e \} = e$ by $h$ codense, hence $a \leq b$. By symmetry, we also have $b \leq a$. Thus $h$ is one-one.

\qed

Proposition 5.1. For separated $L$ and continuous $M$, if $M$ is an image of $L$, then there exist two elements $s, m \in L$ such that $[s \land m, m] \cong M$.

Proof: Given an onto homomorphism $h : L \to M$, let $m \in L$ be the least element such that $h(m) = e$ by Lemma 5.1, and $s \in L$ the largest element such that $h(s) = 0$.

Then $h$ can be factored as

\[ h : \frac{(\_\lor s) \land m}{(\_\lor s)_M \to M}. \]

Now $\tilde{h}$ is dense, codense and onto, therefore $\tilde{h}$ is an isomorphism.

\qed
Remark. This is the frame version of the topological fact that, in a $T_2$ space $X$, every locally compact subspace $A$ is locally closed, that is, $A$ is the intersection of an open subset and a a closed subset of $X$ (see [5]).
