STABILIZATION OF LOCAL PROJECTION TYPE
APPLIED TO CONVECTION-DIFFUSION PROBLEMS
WITH MIXED BOUNDARY CONDITIONS

GUNAR MATTHIES†, PIOTR SKRZYPACZ‡, AND LUTZ TOBISKA†

Abstract. We present the analysis for the local projection stabilization applied to convection-diffusion problems with mixed boundary conditions. We concentrate on the enrichment approach of the local projection methods. Optimal a-priori error estimates will be proved. Numerical tests confirm the theoretical convergence results. Moreover, the local projection stabilization leads to numerical schemes which work well for problems with several types of layers. Away from layers, the solution is captured very well.

Key words. stabilized finite elements, convection-diffusion

AMS subject classifications. 65N12, 65N30

1. Introduction. Convection-diffusion equations occur for instance if physical processes in chemical engineering are modelled. Depending on the problem, different types of boundary conditions are applied on different parts of the domain boundary. A common feature of these problems is the small diffusion coefficient, i.e., the process is convection and/or reaction dominant. Since standard Galerkin discretisations will produce unphysical oscillations for this type of problems, stabilization techniques have been developed. The streamline-upwind Petrov–Galerkin method (SUPG) has been successfully applied to convection-diffusion problems. It was proposed by Hughes and Brooks [19]. One fundamental drawback of SUPG is that several terms which include second order derivatives have to be added to the standard Galerkin discretisation in order to ensure consistency. Alternatively, continuous interior penalty methods [1, 6], residual free bubble methods [10, 11, 12], or subgrid modelling [8, 18] can be used for stabilizing the discretised convection-diffusion problems.

We will focus in this paper on the local projection stabilization. This method has been proposed for the Stokes problem in [3]. The extension to the transport problem was given in [4]. The analysis of the local projection method applied to equal-order interpolation discretisation of the Oseen problem can be found in [5, 23]. We will apply the local projection method to convection-diffusion problems. The stabilization term of the local projection method is based on a projection \( \pi_h : V_h \rightarrow D_h \) of the finite element space \( V_h \) which approximates the solution into a discontinuous space \( D_h \). The standard Galerkin discretisation is stabilized by adding a term which gives \( L^2 \) control over the fluctuation \( id - \pi_h \) of the gradient of the solution.

Originally, the local projection technique was proposed as a two-level method where the projection space \( D_h \) is defined on a coarser grid. The drawback of this approach is an increased discretisation stencil. The general approach given in [13, 23] allows to construct local projection methods, such that the discretisation stencil is not increased compared to the standard Galerkin or the SUPG approach since the approximation space \( Y_h \) and the projection space \( D_h \) are defined on the same mesh. In this case, the approximation space \( Y_h \) is

enriched compared to standard finite element spaces. We will concentrate in this paper on the enrichment approach of the local projection method.

The main objective of this paper is to provide a convergence theory for the local projection method applied to convection-diffusion problems with mixed boundary conditions. For sufficiently regular solutions the same a-priori error estimates which are known for SUPG are proven. Furthermore, several test problems with different types of interior and boundary layers will be presented. They show that the local projection stabilization allows to obtain numerical solutions which capture the solution away from layers.

The plan of this paper is as follows. Section 2 introduces the considered problem class, the weak formulation, and the local projection stabilization. An a-priori error estimate for the stabilized discrete problem will be given in Section 3. Numerical results for problems with different type of layers will be presented in Section 4. Conclusions will be given in Section 5.

We use the following notation in this paper. The convection-diffusion problem is considered in a bounded domain \( \Omega \subset \mathbb{R}^d, d = 2, 3 \), with polygonal or polyhedral boundary \( \partial \Omega \). For a set \( \mathcal{Q} \) which is either a \( d \)-dimensional measurable subset of \( \Omega \) or a \((d-1)\)-dimensional measurable subset of \( \partial \Omega \), the fractional order spaces \( H^s(\mathcal{Q}) \), \( s \in [0, \infty) \) with norm \( \| \cdot \|_{s, \mathcal{Q}} \) and seminorm \( \cdot \|_{s, \mathcal{Q}} \) will be used. For \( s = m \in \mathbb{N}_0 \), the space \( H^s(\mathcal{Q}) \) is defined as the Sobolev space \( W^{m,2}(\mathcal{Q}) \) with norm \( \| \cdot \|_{m, \mathcal{Q}} = \| \cdot \|_{m, \mathcal{Q}} \) and seminorm \( \cdot \|_{s, \mathcal{Q}} = \| \cdot \|_{m, \mathcal{Q}}. \) For non-integer \( s = m + \lambda \) with \( m \in \mathbb{N}_0 \) and \( \lambda \in (0, 1) \), the space \( H^s(\mathcal{Q}) \) is defined as the Sobolev-Slobodeckij space \( W^{m+\lambda,2}(\mathcal{Q}) \), which consists of all functions from the Sobolev space \( W^{m,2}(\mathcal{Q}) \), such that

\[
|v|_{m+\lambda,2, \mathcal{Q}} := \left( \sum_{|\alpha|=m} \int_D \int_D \frac{|D^\alpha v(x) - D^\alpha v(y)|^2}{\|x-y\|^{d+2\lambda}} \, dx \, dy \right)^{1/2} < \infty.
\]

The Sobolev-Slobodeckij space \( W^{m+\lambda,2}(\mathcal{Q}) \) is equipped with the norm

\[
\|v\|_{m+\lambda,2, \mathcal{Q}} := \left( \|v\|_{m,2, \mathcal{Q}}^2 + |v|_{m+\lambda,2, \mathcal{Q}}^2 \right)^{1/2}.
\]

As usual, we set \( \| \cdot \|_{s, \mathcal{Q}} = \| \cdot \|_{m+\lambda,2, \mathcal{Q}} \) and \( \| \cdot \|_{s, \mathcal{Q}} = \| \cdot \|_{m+\lambda,2, \mathcal{Q}}. \) The \( L^2 \) inner product over \( \mathcal{Q} \subset \Omega \) and \( \Gamma \subset \partial \Omega \) will be denoted by \( \langle \cdot, \cdot \rangle_{\mathcal{Q}} \) and \( \langle \cdot, \cdot \rangle_\Gamma \), respectively. In case \( \mathcal{Q} = \Omega \) the index \( \mathcal{Q} \) will be omitted. For \( k \geq 0 \) and a \( d \)-dimensional subset \( \mathcal{S} \subset \Omega \), let \( P_k(\mathcal{S}) \) denote the space of polynomials of degree less than or equal to \( k \) while \( Q_k(\mathcal{S}) \) is the space of all polynomials of degree less than or equal to \( k \) in each variable separately.

Throughout this paper, \( C \) will denote a generic constant which is independent of the mesh and the diffusion parameter \( \varepsilon \). We will use the notation \( \alpha \sim \beta \) if there are positive constants \( C_1 \) and \( C_2 \), such that \( C_1 \beta \leq \alpha \leq C_2 \beta \) holds.

2.1. Weak formulation. We consider the scalar convection-diffusion problem with mixed boundary conditions

\[
\left\{ \begin{array}{ll}
-\varepsilon \Delta u + b \cdot \nabla u + cu = f & \text{ in } \Omega, \\
\quad u = g_D & \text{ on } \Gamma_D, \\
\quad \varepsilon \frac{\partial u}{\partial \mathbf{n}} = g_N & \text{ on } \Gamma_N,
\end{array} \right.
\]

(2.1)

where \( \varepsilon > 0 \) is a small constant. The boundary \( \partial \Omega \) of \( \Omega \) consists of two disjoint parts, the Dirichlet part \( \Gamma_D \) and the Neumann part \( \Gamma_N \). Let \( \Gamma_N \) be a relatively open \( C^1 \) part of \( \partial \Omega \).
and \( \Gamma_D = \partial \Omega \setminus \Gamma_N \). The unit outer normal vector with respect to \( \partial \Omega \) is denoted by \( n \). We are looking for the distribution of concentration \( c \) in \( \Omega \). The reaction coefficient \( c \in L^\infty(\Omega) \) is assumed to be non-negative. Let \( f \in L^2(\Omega) \), \( g_D \in H^{1/2}(\Gamma_D) \), \( g_N \in H^{-1/2}(\Gamma_N) \) be given functions. Furthermore, we require that the convection field \( b \in (W^{1, \infty}(\Omega))^d \) and the reaction coefficient \( c \) fulfill for some \( c_0 > 0 \) the following condition

\[
(2.2) \quad c(x) - \frac{1}{2} \nabla \cdot b(x) \geq c_0 > 0 \quad \forall x \in \overline{\Omega}.
\]

We assume also that the inflow boundary is part of the Dirichlet boundary, i.e.,

\[
(2.3) \quad \{ x \in \partial \Omega : (b \cdot n)(x) < 0 \} \subset \Gamma_D.
\]

We define the function spaces

\[
V = H^1(\Omega) \quad \text{and} \quad V_0 = \{ v \in V : v|_{\Gamma_D} = 0 \}.
\]

A weak formulation of (2.1) reads:

Find \( u \in V \) with \( u|_{\Gamma_D} = g_D \), such that

\[
(2.4) \quad a(u, v) = (f, v) + \langle g_N, v \rangle_{\Gamma_N} \quad \forall v \in V_0,
\]

where the bilinear form \( a : H^1(\Omega) \times H^1(\Omega) \rightarrow \mathbb{R} \) is defined by

\[
(2.5) \quad a(u, v) = \varepsilon (\nabla u, \nabla v) + (b \cdot \nabla u, v) + (cu, v).
\]

The conditions (2.2) and (2.3) guarantee the \( V_0 \)-coercivity of the bilinear form \( a \). The existence and uniqueness of a weak solution of problem (2.4) can be concluded from the Lax–Milgram lemma. For details, we refer to [15].

It is well-known that for pure Dirichlet boundary data, the weak solution of a two-dimensional problem belongs to \( H^2(\Omega) \) provided that the domain is convex; see [16, 17]. However, in general, we can not expect that the weak solution of the problem (2.1) is in \( H^2(\Omega) \). Indeed, in the two-dimensional case, the solution of the Poisson equation \( (\varepsilon = 1, b = c = 0) \) with homogeneous Dirichlet data behaves in the neighbourhoood of a vertex of the boundary with inner angle \( \alpha \) like \( u_1 := r^{\pi/\alpha}\Phi(\varphi) \) and with mixed Dirichlet-Neumann data like \( u_2 := r^{\pi/(2\alpha)}\Phi(\varphi) \). Here, \((r, \varphi)\) denotes a local system of polar coordinates where \( r \) is the distance to the boundary vertex, \( \varphi \in [0, \alpha] \), and \( \Phi(\cdot) \) is a smooth function. From [16, Theorem 1.4.5.3] we conclude that \( u_1 \in H^s \) locally if and only if \( s < \pi/\alpha + 1 \) provided that \( \pi/\alpha \not\in \mathbb{N} \). Analogously, for \( \pi/(2\alpha) \not\in \mathbb{N} \) we get \( u_2 \in H^s \) locally if and only if \( s < \pi/(2\alpha) + 1 \).

### 2.2. Local projection method.

For the finite element discretisation of (2.4), we are given a shape regular family \( \{ T_h \} \) of decomposition of \( \Omega \) into \( d \)-simplices, quadrilaterals, or hexahedra. The diameter of \( K \) will be denoted by \( h_K \) and the mesh size parameter \( h \) is defined by \( h := \max_{K \in \mathcal{T}_h} h_K \). For \( \mathcal{T}_h \), let \( \mathcal{E}_{h,N} \) denote the set of all edges/faces of cells \( K \in \mathcal{T}_h \) which belong to \( \Gamma_N \).

Let \( V_h \subset V \) be a finite element space of continuous elements of order \( r \geq 1 \). We fix the polynomial order \( r \) and the dependence of constants on \( r \) will not be elaborated in this paper. Let

\[
V_{0,h} = \{ v \in V_h : v_h|_{\Gamma_D} = 0 \}
\]

be the discrete test space.
Since the standard Galerkin discretisation of (2.4) lacks generally stability in the convection dominated regime $\varepsilon \ll 1$, unphysical oscillations will appear in the discrete solution. To circumvent this problem, we consider the stabilization by the local projection method. Let $D_h(K), K \in T_h$, be finite dimensional spaces and $\pi_K : L^2(K) \to D_h(K)$ the local $L^2$ projections into $D_h(K)$. The projection space $D_h$ is given by

$$D_h := \bigoplus_{K \in T_h} D_h(K).$$

We define the global projection operator $\pi_h : L^2(\Omega) \to D_h$ by $(\pi_h w)|_K = \pi_K (w|_K)$. The fluctuation operator $\kappa_h : L^2(\Omega) \to L^2(\Omega)$ is given by

$$\kappa_h := i d - \pi_h,$$

where $id : L^2(\Omega) \to L^2(\Omega)$ is the identity mapping in $L^2(\Omega)$. Note that all operators will be applied componentwise to vector-valued functions.

We define the stabilizing term

$$(2.6) \quad S_h(u_h, v_h) := \sum_{K \in T_h} \tau_K (\kappa_h (\nabla u_h), \kappa_h (\nabla v_h))_K,$$

where $\tau_K, K \in T_h$, denote user-defined parameters. Their choice will be discussed later on. Note that the stabilization term $S_h$ gives control over the fluctuation of the gradient. An alternative way is to control by

$$\sum_{K \in T_h} \tau_K (\kappa_h (b \cdot \nabla u_h), \kappa_h (b \cdot \nabla v_h))_K,$$

which represents the fluctuation of the derivative in streamline direction. The proof of the convergence result in the next section shows that we need the assumption $c_0 > 0$ while using the stabilizing term (2.6). For the alternative choice, we can allow $c_0 = 0$ but additional regularity of $b$ has to be assumed; see [23].

We can now state the local projection stabilization of the discretisation of (2.4) as follows:

Find $u_h \in V_h$ with $u_h|_{\Gamma_D} = g_{D,h}$, such that

$$(2.7) \quad a(u_h, v_h) + S_h(u_h, v_h) = (f, v_h) + (g_N, v_h)_{\Gamma_N} \quad \forall v_h \in V_0, h,$$

where $g_{D,h}$ denotes a suitable approximation of $g_D$ which will be discussed in the next section.

The local projection norm

$$(2.8) \quad \|v_h\| := \left\{ \varepsilon \|v_h\|_1^2 + c_0 \|v_h\|_0^2 + \frac{1}{2} \|b \cdot n\|_{1/2}^2 v_h\|_{0, \Gamma_N}^2 + S_h(v_h, v_h) \right\}^{1/2}$$

will be used for our analysis.

The key point in the analysis of local projection methods is the existence of an interpolation operator $j_h$ which provides the usual approximation properties and ensures that the interpolation error is orthogonal to $D_h$. In order to obtain error estimates in the most local form, we are interested in Lagrange interpolation which is defined on continuous functions only. We assume that the solution $u$ of convection-diffusion problem with mixed boundary conditions (2.4) belongs to the Sobolev–Slobodeckij space $H^{1+\lambda}(\Omega)$ with $1 + \lambda > \frac{d}{2}$ which ensures the continuity of $u$. Let $j_h : H^{1+\lambda}(\Omega) \to V_h$ be an interpolation operator with

$$(2.9) \quad \|w - j_h w\|_{0,K} + h_K \|w - j_h w\|_{1,K} \leq Ch_h^{1+\lambda} \|w\|_{1+\lambda, K} \quad \forall w \in H^{1+\lambda}(\Omega),$$
and the following orthogonality relation

\[(w - j_h w, q_h) = 0 \quad \forall q_h \in D_h \quad \forall w \in H^{1+\lambda}(\Omega).\]

We assume that \((j_h w)|_{\Gamma_D}\) depends only on \(w|_{\Gamma_D}\). Let

\[Y_h(K) := \{ u_h|_K : u_h \in V_h \} \cap H^1_0(K)\]

denote the local bubble part of the finite element space \(V_h\) on \(K\).

A sufficient condition for existence of an interpolation operator fulfilling (2.9) and (2.10) provides the following lemma.

**Lemma 2.1 (Local inf-sup condition).** Let \(i_h : H^{1+\lambda}(\Omega) \to V_h, 1 + \lambda > \frac{d}{2}\), be an interpolation operator which provides for all \(K \in \mathcal{T}_h\) the estimate

\[\|w - i_h w\|_{0,K} + h_K \|w - i_h w\|_{1,K} \leq C h^{1+\lambda}_K \|w\|_{1+\lambda,K} \quad \forall w \in H^{1+\lambda}(\Omega).\]

Furthermore, let the local inf-sup condition

\[\exists \beta_1 > 0 \quad \forall h > 0 \quad \forall K \in \mathcal{T}_h : \inf_{q_h \in D_h(K)} \sup_{v_h \in Y_h(K)} \frac{(v_h, q_h)_K}{\|v_h\|_{0,K} \|q_h\|_{0,K}} \geq \beta_1 > 0\]

be satisfied. Then, there exists an interpolation operator \(j_h : H^{1+\lambda}(\Omega) \to V_h\) possessing the approximation property (2.9) and the orthogonality property (2.10).

**Proof.** The construction of the interpolation operator \(j_h\) follows the way presented in the proof of Theorem 2.2 in [23].

The assumed estimate (2.11) holds true for the Lagrangian interpolator \(i_h\) on simplices; see [9]. Combining the ideas of [9] with results given in [24, 22] yields the above estimate on quadrilaterals and hexahedra. Moreover, we obtain

\[\|w - j_h w\|_{0,K} + h_K \|w - j_h w\|_{1,K} \leq C h^{\min(s,r)+1}_K \|w\|_{\min(s,r)+1,K} \quad \forall w \in H^{s+1}(\Omega).\]

If \(P_{r-1}(K) \subset D_h(K)\) holds true for some \(r \geq 1\), then the property of the local \(L^2\) projection \(\pi_K\) and interpolation theory in Sobolev-Slobodeckij spaces give the approximation property

\[\|\kappa_K q\|_{0,K} \leq C h^{\min(s,r)}_K \|q\|_{\min(s,r),K} \quad \forall q \in H^s(K).\]

In order to satisfy the local inf-sup condition (2.12), the local bubble space \(Y_h(K)\) has to be sufficiently large compared to the local projection space \(D_h(K)\). However, the minimal dimension of \(D_h(K)\) is determined indirectly by (2.13).

Several families of pairs \((V_h, D_h)\) of approximation spaces \(V_h\) and projection spaces \(D_h\) which provide the properties (2.9) and (2.10) were given in [23]. We recall here one family on quadrilaterals which was used for our calculations presented in Section 4. Let \(F_K : \hat{K} \to K\) be the multilinear mapping from the reference hyper-cube \(\hat{K} = (-1, 1)^d\) onto the mesh cell \(K \in \mathcal{T}_h\). The projection space \(D_h\) is chosen to be the mapped space

\[P_{r-1,h}^\text{disc} := \{ v \in L^2(\Omega) : v|_K \circ F_K \in P_{r-1}(\hat{K}) \forall K \in \mathcal{T}_h \} .\]

Let

\[\hat{b}(\hat{x}) = \prod_{i=1}^d (1 - \hat{x}_i^2), \quad \hat{x} = (\hat{x}_1, \ldots, \hat{x}_d) \in \hat{K},\]
be the $Q_2$ bubble function defined on $\tilde{K}$. The usual local space $Q_r(\tilde{K})$ is enriched to

$$Q_r^{\text{bubble}}(\tilde{K}) := Q_r(\tilde{K}) \oplus \text{span}(\hat{b} \hat{z}_i^{r-1}, i = 1, \ldots, d).$$

The approximation space $V_h$ is set to

$$Q_r^{\text{bubble}} := \{ v \in H^1(\Omega) : v|_K \circ F_K \in Q_r^{\text{bubble}}(\tilde{K}) \forall K \in \mathcal{T}_h \}.$$

For $r \geq 1$, the finite element pair $(V_h, D_h) = (Q_r^{\text{bubble}}, P_{r-1,h}^{\text{disc}})$ satisfies the inf-sup condition (2.12) of Lemma 2.1 and provides the interpolation error estimate from Lemma 2.1. Hence, there exists an interpolation operator $j_h$ satisfying (2.9) and (2.10). For details, see Lemma 4.2 in [23].

Note that we have $P_{r-1}(K) \not\subset P_{r-1,h}^{\text{disc}}(K)$ for non-affine mappings $F_K : \tilde{K} \to K$ but the approximation property (2.13) holds for successively refined meshes, see [2, 21, 22].

3. Error analysis. Let us first discuss the choice of the discrete Dirichlet boundary condition $g_{D,h} \in \{ v_h|_{\Gamma_D} : v_h \in V_h \}$. We use an interpolation of $g_D$ which fits to the interpolation $j_h$, such that $g_{D,h} = (j_h u)|_{\Gamma_D}$ for the solution $u$ of (2.4). This is possible since the restriction of the standard nodal interpolation onto $\Gamma_D$ depends only on nodal values at $\Gamma_D$. For example, $g_{D,h}$ for the $Q_r^{\text{bubble}}$ discretisation is defined as the $Q_r^{\text{bubble}}$ interpolation of $g_D$ on the boundary $\Gamma_D$.

We continue with solvability of the stabilized discrete problem (2.7).

**Lemma 3.1 (Solvability).** Let $g_{D,h} = (j_h u)|_{\Gamma_D}$. The stabilized discrete problem (2.7) possesses a unique solution.

**Proof.** Since $g_D \in H^{1/2}(\Gamma_D)$ and $g_{D,h} \in \{ v_h|_{\Gamma_D} : v_h \in V_h \}$, we can find some extension $\tilde{g}_{D,h}$, such that $\tilde{g}_{D,h} - u_h \in V_{0,h}$. Indeed, $\tilde{g}_{D,h} = j_h u$ is a possible choice. The key argument for showing the solvability of (2.7) is the proof of the coercivity of the stabilized bilinear form $a + S_h$ with respect to the local projection norm $\| \cdot \|$. Using the conditions (2.2) and (2.3), we obtain for all test functions $v_h \in V_{0,h}$

$$a(v_h, v_h) + S_h(v_h, v_h)$$

$$= \varepsilon \|v_h\|^2 + \frac{1}{2} \int_\Omega b \cdot \nabla v_h^2 \, dx + \int_\Omega c v_h^2 \, dx + S_h(v_h, v_h)$$

$$= \varepsilon \|v_h\|^2 + \frac{1}{2} \int_{\Gamma_N} (b \cdot n) v_h^2 \, ds + \int_\Omega \left( c - \frac{1}{2} \nabla \cdot b \right) v_h^2 \, dx + S_h(v_h, v_h)$$

$$\geq \|v_h\|^2.$$

Hence, the existence and uniqueness of the discrete solution can be concluded from the Lax–Milgram lemma.

We will investigate the consistency error which is caused by adding the stabilizing term $S_h$ to the weak formulation.

**Lemma 3.2 (Consistency error).** Let $u$ and $u_h$ be solutions of the problems (2.4) and (2.7), respectively. Then, the approximated Galerkin orthogonality

$$a + S_h(u - u_h, w_h) = S_h(u, w_h) \quad \forall w_h \in V_{0,h}$$

holds true. Let $\tau_K \sim h_K$ and $u \in H^{1+\lambda}(\Omega)$. Then, the estimate

$$|S_h(u, v_h)| \leq C \left( \sum_{K \in \mathcal{T}_h} h_K^{2(1+\lambda)} \|u\|_{1+\lambda,K}^2 \right)^{1/2} \|v_h\| \quad \forall v_h \in V_h$$
is satisfied. In the case \( u \in H^{s+1}(\Omega), \ s \geq 1 \), the estimate

\[
|S_h(u, v_h)| \leq C \left( \sum_{K \in T_h} h_K^{2 \min(s,r)+1} \|u\|_{\min(s,r)+1,K}^2 \right)^{1/2} \|v_h\| \quad \forall v_h \in V_h
\]

is obtained.

Proof. The relation (3.2) follows by subtracting (2.4) from (2.7). The Cauchy–Schwarz inequality implies

\[
|S_h(u, v_h)| \leq S_h(u, u)^{1/2} S_h(v_h, v_h)^{1/2}
\]

where the definition (2.6) of \( S_h \) was used. For \( u \in H^{1+\lambda}(\Omega) \), it follows from (2.13) and \( \tau_K \sim h_K \) that

\[
S_h(u, u) = \sum_{K \in T_h} \tau_K \|\kappa_h(\nabla u)\|_{0_K}^2 \leq C \sum_{K \in T_h} h_K^{2\lambda+1} \|u\|_{1+\lambda,K}^2.
\]

Hence, we have

\[
|S_h(u, v_h)| \leq C \left( \sum_{K \in T_h} h_K^{2\lambda+1} \|u\|_{1+\lambda,K}^2 \right)^{1/2} \|v_h\|
\]

and the second assertion is proved. The last statement of this lemma follows analogously.

Using the previous estimates, we are now able to formulate and prove our main convergence result.

**Theorem 3.3 (A-priori error estimate).** Assume \( \tau_K \sim h_K \). Let \( u \in H^{1+\lambda}(\Omega) \) and \( u_h \in V_h \) be the solutions of problems (2.4) and (2.7), respectively. Then, the a-priori error estimate

\[
\|u - u_h\| \leq C \left( \sum_{K \in T_h} (\varepsilon + h_K) h_K^{2\lambda} \|u\|_{1+\lambda,K}^2 \right)^{1/2}
\]

holds true. If in addition \( u \in H^{s+1}(\Omega), \ s \geq 1 \), then the estimate

\[
\|u - u_h\| \leq C \left( \sum_{K \in T_h} (\varepsilon + h_K) h_K^{2 \min(s,r)} \|u\|_{\min(s,r)+1,K}^2 \right)^{1/2}
\]

is fulfilled.

Proof. First, the triangle inequality implies

\[
\|u - u_h\| \leq \|u - j_h u\| + \|j_h u - u_h\|.
\]

In order to proceed with the estimate of the interpolation error in the local projection norm, we provide some auxiliary results concerning the interpolation error on edges/faces and the fluctuation operator. We note the following trace estimate on any edge/faces:

\[
\|v\|_0, E \leq Ch_k^{1/2} \|v\|_{1,K} + Ch_k^{-1/2} \|v\|_{0,K} \quad \forall v \in H^1(K),
\]
which gives immediately the local interpolation error estimate

\[(3.9) \quad \|j_h u - u\|_{0, E} \leq C h^{1+\lambda/2}_K \|u\|_{1+\lambda, K} \]

on an edge/face \( E \subset \partial K \). Furthermore, one can show for \( b \in (W^{1,\infty}(K))^d \) the estimate

\[(3.10) \quad \|\kappa_h (b \cdot \nabla v_h)\|_{0, K} \leq C \|b\|_{1,\infty, K} \|v_h\|_{0, K} + \|b\|_{0,\infty, K} \|\kappa_h (\nabla v_h)\|_{0, K} \]

see the proof of Corollary 2.14 in [23].

Using the interpolation error estimates (2.9) and (3.9), the fact \( b \in (W^{1,\infty}(\Omega))^d \), and the \( L^2 \) stability of the fluctuation operator \( \kappa_h \), we conclude

\[(3.11) \quad \|u - j_h u\| \leq C \left( \sum_{K \in T_h} (\varepsilon + h^2_K + \tau_K) h^{2\lambda}_K \|u\|_{1+\lambda, K}^2 \right)^{1/2} \]

In order to estimate the second error term on the right hand side of (3.7), we use \( u_h|_{\Gamma_D} = (j_h u)|_{\Gamma_D} \) and the \( V_0, h \) coercivity proved in Lemma 3.1. We obtain by using relation (3.2) from Lemma 3.2

\[(3.12) \quad \|j_h u - u_h\|^2 \leq a(j_h u - u_h, w_h) + S_h(j_h u - u_h, w_h) - a(j_h u - u, w_h) + S_h(j_h u - u, w_h), \]

where we set \( w_h := j_h u - u_h \) for abbreviation.

We start by estimating the first term on the right hand side of (3.12). Using the Cauchy–Schwarz inequality, the interpolation property (2.9) of \( j_h \) and the fact \( c \in L^\infty(\Omega) \), it follows that

\[(3.13) \quad \varepsilon (\nabla (j_h u - u), \nabla w_h) + (c(j_h u - u), w_h) \leq C \left( \sum_{K \in T_h} (\varepsilon + h^2_K) h^{2\lambda}_K \|u\|_{1+\lambda, K}^2 \right)^{1/2} \|w_h\|. \]

In order to estimate the convective term in the bilinear form \( a \), we integrate by parts and obtain

\[(3.14) \quad \langle b \cdot \nabla (j_h u - u), w_h \rangle = -\langle j_h u - u, b \cdot \nabla w_h \rangle - \langle j_h u - u, w_h (\nabla \cdot b) \rangle + \langle (b \cdot n) (j_h u - u), w_h \rangle_{\Gamma_N}. \]

The three terms will be estimated separately. Using the orthogonality property (2.10) of the interpolation operator \( j_h \), we get

\[(j_h u - u, b \cdot \nabla w_h) = (j_h u - u, b \cdot \nabla w_h) - (j_h u - u, \kappa_h (b \cdot \nabla w_h)) = (j_h u - u, \kappa_h (b \cdot \nabla w_h)). \]
Using (3.10) and the approximation property (2.9), we estimate
\[
\left| (j_h u - u, b \cdot \nabla w_h) \right| \leq \sum_{K \in T_h} \| j_h u - u \|_{0, K} \| \kappa_h (b \cdot \nabla w_h) \|_{0, K}
\leq C \sum_{K \in T_h} h_K^{1+\lambda} \| u \|_{1+\lambda, K} \left( \| w_h \|_{0, K} + \| \kappa_h (\nabla w_h) \|_{0, K} \right)^{1/2}
\leq C \left( \sum_{K \in T_h} h_K^{2+2\lambda} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \| w_h \|_0
+ C \left( \sum_{K \in T_h} h_K^{2+2\lambda} \tau_K^{-1} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \left( \sum_{K \in T_h} \tau_K \| \kappa_h (\nabla w_h) \|_{0, K}^2 \right)^{1/2}
\]
and we obtain
\[
\left| (j_h u - u, b \cdot \nabla w_h) \right| \leq C \left( \sum_{K \in T_h} h_K^{1+2\lambda} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \| w_h \|_0,
\]
where \( C_0 > 0 \) and the choice \( \tau_K \sim h_K \) were exploited.

The second term in (3.14) can be estimated as follows
\[
\left| (j_h u - u, w_h (\nabla \cdot b)) \right| \leq C \left( \sum_{K \in T_h} h_K^{2+2\lambda} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \| w_h \|_0,
\]
where the interpolation error estimate (2.9), \( b \in (W^{1,\infty}(\Omega))^d \), and \( C_0 > 0 \) were used.

Applying (3.9), the last term in (3.14) can be estimated as
\[
\langle (b \cdot n) (j_h u - u), w_h \rangle_{\Gamma_N} = \sum_{E \in E_{h,N}} \| b \cdot n \|_{1/2} \left( \sum_{u \in E} (j_h u - u) \right) \| b \cdot n \|_{1/2} \| w_h \|_0, E
\leq C \left( \sum_{K \in T_h} h_K^{2\lambda+1} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \| w_h \|_0,
\]
where the shape regularity of \( T_h \) and \( b \in (W^{1,\infty}(\Omega))^d \) were exploited. Putting together the estimates (3.15), (3.16), and (3.17), we get the bound
\[
\left| (b \cdot \nabla (j_h u - u), w_h) \right| \leq C \left( \sum_{K \in T_h} h_K^{2\lambda+1} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \| w_h \|_0
\]
for the convective terms in the bilinear form \( a \). Using (3.13) and (3.18), we conclude that
\[
\left| a (j_h u - u, w_h) \right| \leq C \left( \sum_{K \in T_h} (\varepsilon + h_K) h_K^{2\lambda} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \| w_h \|_0
\]
holds true.

The second term on the right hand side of (3.12) can be handled by Lemma 3.2. We get
\[
\left| S_h (u, w_h) \right| \leq C \left( \sum_{K \in T} h_K^{2\lambda+1} \| u \|_{1+\lambda, K}^2 \right)^{1/2} \| w_h \|_0.
\]
To estimate the third term of (3.12), we use the Cauchy–Schwarz inequality, the \(L^2\) stability of the fluctuation operator \(\kappa_h\), the parameter choice \(\tau_K \sim h_K\), and the approximation property (2.9) of the interpolation operator \(j_h\). We obtain

\[
S_h(j_h u - u, w_h) \leq S_h(j_h u - u, j_h u - u)^{1/2} S_h(w_h, w_h)^{1/2} \\
\leq \left\{ \sum_{K \in \mathcal{T}_h} \tau_K \| \kappa_h (\nabla(j_h u - u)) \|_{0,K}^2 \right\}^{1/2} \| w_h \| \\
\leq C \left( \sum_{K \in \mathcal{T}_h} h_K^{2\lambda+1} \| u \|_{1+\lambda,K}^2 \right)^{1/2} \| w_h \|.
\]

(3.21)

Using (3.12) and the estimates (3.19), (3.20), (3.21), we obtain

\[
\| j_h u - u \| \leq C \left( \sum_{K \in \mathcal{T}_h} (\varepsilon + h_K) h_K^{2\lambda} \| u \|_{1+\lambda,K}^2 \right)^{1/2}.
\]

Combining this with (3.7) and (3.11) yields the assertion (3.5). The estimate for the case \(u \in H^{s+1}(\Omega)\) follows the same lines.

4. Numerical examples. This section will present some numerical results for the local projection stabilization applied to convection-diffusion problem. All numerical calculations were performed with the finite element package MooNMD [20].

We consider problems on the unit square \(\Omega = (0,1)^2\). Our calculations were carried out on quadrilateral meshes which were obtained by successive regular refinement of an initial coarse grid (level 0) consisting of 4 \(\times\) 4 congruent squares. The number of degrees of freedom for different enriched finite element spaces are given in Table 4.1. It is clearly to see that the number of dofs increases by a factor of about 4 from one mesh level to the next finer one.

Since \(\tau_K \sim h_K\), compare Theorem 3.3, the stabilization parameters are chosen as follows

\[
\tau_K := \tau_0 h_K \quad \forall K \in \mathcal{T}_h,
\]

where \(\tau_0 > 0\) denotes a constant which will be fixed for each of the test problems presented in this section.

We will investigate in this section the behaviour of the local projection stabilization applied to problems with different kinds of solutions. The presented examples, except the first one, can be found in [7, 26].

4.1. Smooth solution. We start with a problem which has a smooth solution and check the convergence orders which were predicted by Theorem 3.3. Let
\[ \varepsilon = 10^{-7}, \quad \mathbf{b} = (2, 3)^T, \quad c = 1, \]
and
\[ \Gamma_N := \{(x, y) \in \partial \Omega : x = 1, \ 0 < y < 1\}, \quad \Gamma_D := \partial \Omega \setminus \Gamma_N. \]
The right hand side \( f \), the Dirichlet boundary condition \( g_D \) on \( \Gamma_D \), and the Neumann boundary condition \( g_N \) on \( \Gamma_N \) are chosen, such that
\[ u(x, y) = \sin(\pi x) \sin(\pi y) \]
is the solution of (2.1). Table 4.2 shows for the enriched quadrilateral elements of first, second, and third order the error in the local projection norm \( \| \cdot \| \) on different levels where \( \tau_0 = 0.1 \) was used. We see that the predicted convergence order of \( r + 1/2 \) is achieved in all cases. Moreover, we see that higher order finite elements give much more accurate results with less unknowns.

4.2. Solution with exponential layer. We will study now the behaviour of the local projection stabilization for a problem with an exponential boundary layer. Let
\[ \varepsilon = 10^{-7}, \quad \mathbf{b} = (0, 2)^T, \quad c = 0, \]
and
\[ \Gamma_D := \partial \Omega, \quad \Gamma_N := \emptyset. \]
The right hand side \( f \) and the Dirichlet boundary condition \( g_D \) are chosen, such that
\[ u(x, y) = (2x - 1) \frac{1 - \exp \left( \frac{2(1-y)}{\varepsilon} \right)}{1 - \exp \left( \frac{-2}{\varepsilon} \right)} \]
is the solution of (2.1). Note that the solution \( u \) exhibits an exponential boundary layer at \( y = 1 \). Figure 4.1 shows for the choice \( \tau_0 = 0.1 \) the numerical solution which was obtained by using the approximation space \( Q_{1,h}^{\text{bubble}} \) and the projection space \( P_{0,h}^{\text{disc}} \). Note that here and in all subsequent figures only the nodal values at the cell vertices are shown, i.e., the additional bubble part of the solution will not be shown. We see that the numerical solution shows no oscillations in the whole domain. Away from the exponential boundary layer, the numerical solution approximates the function \( 2x - 1 \) which is the solution of the reduced problem.
**4.3. Solution with interior and exponential layers.** Our next problem is a benchmark for problems with an interior layer and an exponential layer. Let

$$\varepsilon = 10^{-7}, \quad b = (8xy(1-x), -4(2x-1)(1-y^2))^T, \quad c = 0,$$

and

$$\Gamma_N := \{(x, y) \in \partial \Omega : 1/2 < x < 1, y = 0\}, \quad \Gamma_D := \partial \Omega \setminus \Gamma_N.$$ 

We prescribe on Dirichlet boundary \(\Gamma_D\) the piecewise constant function

$$g_D(x, y) = \begin{cases} 1 & \text{for } 1/4 \leq x \leq 1/2, \ y = 0, \\ 1 & \text{for } 0 \leq y \leq 1, \ x = 1, \\ 0 & \text{otherwise}, \end{cases}$$

while the homogeneous Neumann condition \(g_N = 0\) will be used on \(\Gamma_N\). The right hand side in (2.1) is given by \(f = 0\). The numerical solution for \(\tau_0 = 0.01\) is presented in Figure 4.2.

It shows overshoots and undershoots near the interior layer and exponential boundary layer. This seems to be a common feature of many stabilization techniques; see [25]. However, the solution obtained by the local projection stabilization has no oscillations away from the...
layer. Furthermore, the position of the layers is captured very well. There are no significant differences between the numerical solutions obtained by using the stabilizing term (2.6) or its alternative based on the fluctuations of the derivatives in streamline direction; see Figure 4.3.

4.4. Solution with parabolic layers. The solution of our last example exhibits two parabolic boundary layers. Let

\[ \varepsilon = 10^{-7}, \quad b = (0, 1 + x^2)^T, \quad c = 0, \]

and

\[ \Gamma_N := \{(x, y) \in \partial \Omega : 0 < x < 1, \ y = 1\}, \quad \Gamma_D := \partial \Omega \setminus \Omega_N. \]

We use homogeneous Neumann condition \( g_N = 0 \) on \( \Gamma_N \) while the Dirichlet boundary condition \( g_D \) on \( \Gamma_D \) is given by

\[ g_D = \begin{cases} 1 & \text{for } 0 \leq x \leq 1, \ y = 0, \\ 1 - y & \text{otherwise}. \end{cases} \]

Furthermore, the right hand side of (2.1) is \( f = 0 \). Note that the solution of (2.1) exhibits parabolic layers at the vertical walls \( x = 0 \) and \( x = 1 \). The pictures in Figure 4.4 show the obtained result for \( \tau_0 = 0.01 \). We see that the parabolic boundary layers are well captured. Overshoots and undershoots occur only near the layers while the solution has no oscillations away from the layer.

We are finally interested in the influence of the size of the stabilization parameter \( \tau_K \) on the solution. To this end, we will vary the constant \( \tau_0 \) in \( \tau_K = \tau_0 h_K \). For simplicial meshes and piecewise linears enriched with cubic bubbles, it is known that the elimination of the bubble part leads to the SUPG method where the stabilization parameters of both methods act in an inverse way; see [14]. For quadrilaterals, it is an open question and needs further theoretical studies. Exemplarily, we plot the solution on the outflow boundary. We start with calculation for the pair \( (Q_{1,b}^{\text{bubble}}, P_0^{\text{disc}}) \). The graphs in Figure 4.5 show that too small values for \( \tau_0 \) result in oscillations while too large values for \( \tau_0 \) cause a smearing of the layer. If the constant \( \tau_0 \) is chosen suitably then the solution is captured very well on almost the whole edge. This means that the remaining small oscillations concentrate near the boundary and only a little smearing takes place.
Using the pair \( (Q_{2, h}^{\text{bubble}}, P_{1, h}^{\text{disc}}) \), the situation changes. Even for the quite small stabilization parameter \( \tau_0 = 0.01 \), the solution shows no oscillations in the nodal values at the vertices; see Figure 4.6. One reason for this behaviour might be the additional stability which is already introduced by the presence of bubble functions in \( Q_{2, h}^{\text{bubble}} \).

5. Conclusions. We have presented and analysed a stabilized finite element method for solving convection-diffusion problems. The stabilization was achieved by applying the local projection technique which gives additional control over the fluctuation of the gradient. Our analysis handles mixed boundary conditions. The given a-priori error estimate gives qualita-
\[ x = 10^{-4} \]
\[ t_0 = 10^{-2} \]
\[ t_0 = 10^{-1} \]

**FIG. 4.6.** Example 4.4 with \((V_h, D_h) = (Q_{1, 0}^{\text{bubble}}, P_{1, 0}^{\text{div}}): \) Influence of parameter \( t_0 \) on the behaviour of outflow profile.

Generally the same result as other stabilization techniques like the streamline diffusion method. The numerical results presented in Section 4 show that stabilization by local projection is well suited for problems with layers of different kind. The last example indicates that the size of the stabilization parameter has for first order elements an important influence on the quality of the numerical solution while the dependence is much smaller for second order elements.
