**ABSTRACT.** A strong form of continuity, called  $\theta$ -R-continuity, is introduced. It is shown that  $\theta$ -R-continuity is stronger than R-continuity. Relationships between  $\theta$ -R-continuity and various closed graph properties are investigated. Additional properties of  $\theta$ -R-continuous functions are established.

**KEY WORDS AND PHRASES.**  $\theta$ -R-continuity, R-continuity, closed graph property,  $\theta$ -C-closed, almost-regular.

**1980 AMS SUBJECT CLASSIFICATION CODE.** 54C10, 54D10.

### 1. INTRODUCTION.

In this paper a strong form of continuity, which we call  $\theta$ -R-continuity, is introduced. This form of continuity is stronger than R-continuity developed by Konstadilaki-Savvopoulou and Janković in [1]. As is the case for R-continuity,  $\theta$ -R-continuity is closely related to regularity and the closed graph property. For example, the range of a  $\theta$ -R-continuous function is  $R_1$  and a  $\theta$ -R-continuous function into a  $T_1$ -space satisfies a strong form of the closed graph property. Many of the results in Konstadilaki-Savvopoulou and Janković [1] carry over, with some modification, to  $\theta$ -R-continuous functions. However, one result in [1] is extended to  $\theta$ -R-continuous functions.

### 2. PRELIMINARIES.

The symbols  $X$ ,  $Y$ , and  $Z$  represent topological spaces with no separation axioms assumed unless explicitly stated. For a subset  $A$  of a space  $X$  the closure of  $A$ , interior of  $A$ , and boundary of  $A$  are denoted by  $Cl A$ ,  $Int A$ , and  $Bd A$ , respectively. The  $\theta$ -closure of  $A$ , denoted by  $Cl_{\theta} A$ , is the set of all  $x$  in  $X$  such that every closed neighborhood of  $x$  intersects  $A$  nontrivially. A set  $A$  is  $\theta$ -closed provided that  $A = Cl_{\theta} A$  and a set is  $\theta$ -open if its complement is

$\theta$ -closed. A set  $A$  is regular open (resp. regular closed) if  $\text{Int Cl } A = A$  (resp.  $\text{Cl Int } A = A$ ). If  $\mathcal{F}$  is a filter base on a space  $X$ , then by  $\text{Cl}_\theta \mathcal{F}$  we mean the filter base  $\{\text{Cl}_\theta F : F \in \mathcal{F}\}$ .

**DEFINITION 1.** A function  $f: X \rightarrow Y$  is  $R$ -continuous (Konstadilaki-Savvopoulou and Jankovic [1]) (resp. strongly  $\theta$ -continuous (Long and Herrington [2]), weakly continuous (Levine [3])) if for every  $x \in X$  and every open subset  $V$  of  $Y$  containing  $f(x)$ , there exists an open subset  $U$  of  $X$  containing  $x$  such that  $\text{Cl } f(U) \subseteq V$  (resp.  $f(\text{Cl } U) \subseteq V$ ,  $f(U) \subseteq \text{Cl } V$ ).

### 3. RELATIONSHIPS TO OTHER CONTINUITY CONDITIONS.

We define a function  $f: X \rightarrow Y$  to be  $\theta$ - $R$ -continuous if for each  $x \in X$  and each open subset  $V$  of  $Y$  containing  $f(x)$ , there exists an open subset  $U$  of  $X$  containing  $x$  for which  $\text{Cl}_\theta f(U) \subseteq V$ . The following theorem characterizes  $\theta$ - $R$ -continuity in terms of filter bases. The proof is straightforward and is omitted.

**THEOREM 1.** A function  $f: X \rightarrow Y$  is  $\theta$ - $R$ -continuous if and only if for every filter base  $\mathcal{F}$  on  $X$ , if  $\mathcal{F}$  converges to  $x$  in  $X$ , then the filter base  $\text{Cl}_\theta f(\mathcal{F})$  converges to  $f(x)$  in  $Y$ .

Since for any set  $A$   $\text{Cl } A \subseteq \text{Cl}_\theta A$ ,  $\theta$ - $R$ -continuity implies  $R$ -continuity (and hence implies continuity). The following example shows that the converse implication fails.

**EXAMPLE 1.** Let  $X = \{a, b, c, d\}$ ,  $\mathcal{T} = \{X, \emptyset, \{c\}, \{c, d\}, \{a, b, c\}\}$  and  $f: (X, \mathcal{T}) \rightarrow (X, \mathcal{T})$  be the constant map  $f(x) = a$  for each  $x \in X$ . It is easily checked that  $f$  is  $R$ -continuous but not  $\theta$ - $R$ -continuous.

Since in a regular space the closure and  $\theta$ -closure operators agree, obviously if  $f: X \rightarrow Y$  is  $R$ -continuous and  $Y$  is regular, then  $f$  is  $\theta$ - $R$ -continuous. Also because the closure and  $\theta$ -closure operators agree on open sets, it follows that if  $f: X \rightarrow Y$  is  $R$ -continuous and open, then  $f$  is  $\theta$ - $R$ -continuous.  $R$ -continuity (and hence  $\theta$ - $R$ -continuity) implies strong  $\theta$ -continuity (Konstadilaki-Savvopoulou and Jankovic [1]). The following theorem establishes conditions under which this implication can be reversed.

**DEFINITION 2.** Jankovic and Rose [4]. A function  $f: X \rightarrow Y$  is weakly  $\theta$ -closed provided there exists an open basis  $\mathcal{B}$  for the topology on  $X$  for which  $\text{Cl}_\theta f(U) \subseteq f(\text{Cl } U)$  for every  $U \in \mathcal{B}$ .

**THEOREM 2.** If  $f: X \rightarrow Y$  is strongly  $\theta$ -continuous and weakly  $\theta$ -closed, then  $f$  is  $\theta$ - $R$ -continuous.

**PROOF.** Let  $x \in X$  and let  $V$  be an open subset of  $Y$  containing  $f(x)$ . Since  $f$  is strongly  $\theta$ -continuous, there exists an open subset  $U$  of  $X$  containing  $x$  for which  $f(\text{Cl } U) \subseteq V$ . Let  $\mathcal{B}$  be an open basis for the topology on  $X$  such that  $\text{Cl}_\theta f(W) \subseteq f(\text{Cl } W)$  for every  $W \in \mathcal{B}$ . We may assume  $U \in \mathcal{B}$ . Thus  $\text{Cl}_\theta f(U) \subseteq f(\text{Cl } U) \subseteq V$  and hence  $f$  is  $\theta$ - $R$ -continuous.  $\square$

In Konstadilaki-Savvopoulou and Jankovic [1] it is proved that a continuous function from a locally compact Hausdorff Space into a Hausdorff space is  $R$ -continuous. We shall prove that under these conditions the function is actually  $\theta$ - $R$ -continuous. The essential reason is that a compact subset of a Hausdorff space is  $\theta$ -closed.

Except for the use of this fact, the proof is the same as in Konstadilaki-Savvopoulou and Jankovic [1].

**THEOREM 3.** If  $f: X \rightarrow Y$  is continuous,  $X$  is locally compact Hausdorff, and  $Y$  is Hausdorff, then  $f$  is  $\theta$ -R-continuous.

**PROOF.** Since  $X$  is locally compact Hausdorff,  $X$  is regular and therefore  $f$  is strongly  $\theta$ -continuous. From the local compactness of  $X$ , we obtain an open basis  $\mathcal{B}$  for the topology on  $X$  consisting of sets with compact closures. Let  $U \in \mathcal{B}$ . Since  $f$  is continuous,  $f(\text{Cl } U)$  is compact in  $Y$  and hence  $\theta$ -closed because  $Y$  is Hausdorff. Thus  $\text{Cl}_\theta f(U) \subseteq \text{Cl}_\theta f(\text{Cl } U) = f(\text{Cl } U)$ . Therefore  $f$  is weakly  $\theta$ -closed and hence by Theorem 2  $f$  is  $\theta$ -R-continuous.  $\square$

#### 4. CLOSED GRAPH PROPERTIES.

From Konstadilaki-Savvopoulou and Jankovic [1] the graph of an  $R$ -continuous function into a  $T_1$ -space is  $\theta$ -closed with respect to the domain. In this section an analogous result is proved for  $\theta$ -R-continuous functions.

**DEFINITION 3.** Baker [5]. A subset  $U$  of a space  $X$  is  $\theta$ -C-open provided there exists a subset  $A$  of  $X$  for which  $U = X - \text{Cl}_\theta A$ .

**DEFINITION 4.** Let  $f: X \rightarrow Y$  be a function. The graph of  $f$ , denoted by  $G(f)$ , is  $\theta$ -C-closed with respect to  $X$  if for each  $(x, y) \notin G(f)$  there exist subsets  $U$  and  $V$  of  $X$  and  $Y$ , respectively, with  $x \in U$ ,  $y \in V$ ,  $U$  open,  $V$   $\theta$ -C-open, and  $((\text{Cl } U) \times V) \cap G(f) = \emptyset$  (or equivalently  $f(\text{Cl } U) \cap V = \emptyset$ ).

**THEOREM 4.** If  $f: X \rightarrow Y$  is  $\theta$ -R-continuous and  $Y$  is  $T_1$ , then  $G(f)$  is  $\theta$ -C-closed with respect to  $X$ .

**PROOF.** Assume  $(x, y) \notin G(f)$ . Since  $y \neq f(x)$  and  $Y$  is  $T_1$ , there exists an open subset  $V$  of  $Y$  such that  $f(x) \in V$  and  $y \notin V$ . The  $\theta$ -R-continuity of  $f$  implies the existence of an open subset  $U$  of  $X$  containing  $x$  such that  $\text{Cl}_\theta f(U) \subseteq V$ . Therefore  $(x, y) \in (\text{Cl } U) \times (Y - \text{Cl}_\theta f(U))$  which is disjoint from  $G(f)$  because if  $a \in \text{Cl } U$ , then  $f(a) \in f(\text{Cl } U) \subseteq \text{Cl } f(U) \subseteq \text{Cl}_\theta f(U)$ . Note that  $Y - \text{Cl}_\theta f(U)$  is  $\theta$ -C-open.  $\square$

Next we establish conditions under which a weak form of continuity and some type of closed graph property imply  $\theta$ -R-continuity.

**DEFINITION 5.** Jankovic and Rose [4]. The graph of a function  $f: X \rightarrow Y$  is  $\theta$ -closed with respect to  $Y$  if for each  $(x, y) \notin G(f)$ , there exist open subsets  $U$  and  $V$  of  $X$  and  $Y$ , respectively, with  $x \in U$ ,  $y \in V$ , and  $(U \times \text{Cl } V) \cap G(f) = \emptyset$  (or equivalently  $f(U) \cap \text{Cl } V = \emptyset$ ).

**DEFINITION 6.** Singal and Arya [6]. A space  $X$  is almost-regular if each regular closed set  $C$  and each  $x \in X - C$  can be separated by disjoint open subsets of  $X$ .

The assumption that the codomain is almost-regular is required in several of the following theorems. Note that under this assumption,  $\theta$ -R-continuity is not equivalent to  $R$ -continuity. The space in Example 1 is almost-regular whereas the function is  $R$ -continuous but not  $\theta$ -R-continuous.

From Jankovic and Rose [4] we have that a space  $X$  is almost-regular if and only if regular closed sets are  $\theta$ -closed. This fact is used in the following proof.

DEFINITION 7. Konstadilaki-Savvopoulou and Jankovic [1]. A space  $X$  is rim-compact provided there exists an open basis for the topology on  $X$  consisting of sets with compact boundaries.

THEOREM 5. If  $f: X \rightarrow Y$  is weakly continuous and has a  $\theta$ -closed graph with respect to  $Y$  and  $Y$  is rim-compact and almost-regular, then  $f$  is  $\theta$ -R-continuous.

PROOF. Let  $x \in X$  and let  $V$  be an open subset of  $X$  containing  $f(x)$ . Since  $Y$  is rim-compact, there exists an open subset  $W$  of  $Y$  for which  $f(x) \in W \subseteq V$  and  $Bd W$  is compact. The weak continuity of  $f$  implies the existence of an open subset  $U$  of  $X$  containing  $x$  such that  $f(U) \subseteq Cl W$ .

Let  $y \in Bd W$ . Since  $f(x) \in W$  and  $W \cap Bd W = \emptyset$ ,  $(x, y) \notin G(f)$ . Because  $G(f)$  is  $\theta$ -closed with respect to  $Y$ , there exist open subsets  $A_y$  and  $B_y$  of  $X$  and  $Y$ , respectively, for which  $x \in A_y$ ,  $y \in B_y$ , and  $f(A_y) \cap Cl B_y = \emptyset$ . It follows that  $(Cl_{\theta} f(A_y)) \cap B_y = \emptyset$ .

The collection  $\{B_y : y \in Bd W\}$  is an open cover of  $Bd W$ , which is compact. Hence there is a finite collection  $\{B_{y_i} : i = 1, 2, \dots, n\}$  for which  $Bd W \subseteq \cup \{B_{y_i} : i = 1, 2, \dots, n\}$ . Let  $U_0 = U \cap (\cap \{A_{y_i} : i = 1, 2, \dots, n\})$ . Then  $Cl_{\theta} f(U_0) \subseteq Cl_{\theta} f(\cap \{A_{y_i} : i = 1, 2, \dots, n\}) \subseteq Cl_{\theta} \cap \{f(A_{y_i}) : i = 1, 2, \dots, n\} \subseteq \cap \{Cl_{\theta} f(A_{y_i}) : i = 1, 2, \dots, n\}$  which is disjoint from  $\cup \{B_{y_i} : i = 1, 2, \dots, n\}$  and hence disjoint from  $Bd W$ . Therefore  $(Cl_{\theta} f(U_0)) \cap Bd W = \emptyset$ . However,  $Cl_{\theta} f(U_0) \subseteq Cl_{\theta} f(U) \subseteq Cl_{\theta} Cl W = Cl W$ . (This last equality follows from the fact that  $Cl W$  is regular closed and  $Y$  is almost-regular.) Thus we have that  $Cl_{\theta} f(U_0) \subseteq (Cl W) - Bd W \subseteq W \subseteq V$  and therefore  $f$  is  $\theta$ -R-continuous.  $\square$

##### 5. ADDITIONAL PROPERTIES.

In Konstadilaki-Savvopoulou and Jankovic [1] it is proved that a function  $f: X \rightarrow Y$  is R-continuous if and only if for every  $x \in X$  and every closed subset  $F$  of  $Y$  with  $f(x) \notin F$ , there exist open subsets  $U$  and  $V$  of  $X$  and  $Y$ , respectively, such that  $x \in U$ ,  $F \subseteq V$ , and  $f(U) \cap V = \emptyset$ . The following three theorems are analogous results for  $\theta$ -R-continuous functions.

THEOREM 6. If  $f: X \rightarrow Y$  is  $\theta$ -R-continuous, then for every  $x \in X$  and every closed subset  $F$  of  $Y$  such that  $f(x) \notin F$ , there exists an open subset  $U$  of  $X$  containing  $x$  and a  $\theta$ -C-open subset  $V$  of  $Y$  with  $F \subseteq V$  such that  $f(Cl U) \cap V = \emptyset$ .

PROOF. Let  $x \in X$  and let  $F$  be a closed subset of  $Y$  with  $f(x) \in X - F$ . There exists an open subset  $U$  of  $X$  containing  $x$  such that  $Cl_{\theta} f(U) \subseteq Y - F$ . Let  $V = Y - Cl_{\theta} f(U)$ . Then  $V$  is  $\theta$ -C-open and  $F \subseteq V$ . Since  $f$  is continuous,  $f(Cl U) \subseteq Cl f(U) \subseteq Cl_{\theta} f(U)$ . Therefore  $f(Cl U) \cap V = \emptyset$ .  $\square$

If the condition that  $V$  be  $\theta$ -C-open is replaced with the stronger requirement that  $V$  be  $\theta$ -open, then the implication in Theorem 6 can be reversed.

THEOREM 7. Let  $f: X \rightarrow Y$  be a function. If for every  $x \in X$  and every closed subset  $F$  of  $Y$  with  $f(x) \notin F$  there exists an open subset  $U$  of  $X$  containing  $x$  and a  $\theta$ -open subset  $V$  of  $Y$  with  $F \subseteq V$  such that  $f(U) \cap V = \emptyset$ , then  $f$  is  $\theta$ -R-continuous.

PROOF. Let  $x \in X$  and let  $V$  be an open subset of  $Y$  with  $f(x) \in V$ . Let  $F = Y - V$ . Since  $f(x) \notin F$ , there exists an open subset  $U$  of  $X$  containing  $x$  and a  $\theta$ -open subset  $W$  of  $Y$  with  $F \subseteq W$  and  $f(U) \cap W = \emptyset$ . Then  $f(U) \subseteq Y - W$ . Thus  $\text{Cl}_\theta f(U) \subseteq \text{Cl}_\theta (Y - W) = Y - W \subseteq Y - F = V$ . Therefore  $f$  is  $\theta$ -R-continuous.  $\square$

In an almost-regular space  $\text{Cl}_\theta \text{Cl}_\theta A = \text{Cl}_\theta A$  for any set  $A$  (Jankovic' and Rose [4]). It follows that in a almost-regular space  $\theta$ -C-openness is equivalent to  $\theta$ -openness. Therefore we have the following result.

**THEOREM 8.** Let  $X$  and  $Y$  be topological spaces with  $Y$  almost-regular. Then  $f: X \rightarrow Y$  is  $\theta$ -R-continuous if and only if for every  $x \in X$  and every closed subset  $F$  of  $Y$  with  $f(x) \notin F$ , there exist an open subset  $U$  of  $X$  containing  $x$  and an  $\theta$ -C-open subset  $V$  of  $Y$  with  $F \subseteq V$  such that  $f(U) \cap V = \emptyset$ .

In the definition of R-continuity the condition " $\text{Cl} f(U) \subseteq V$ " can be replaced with " $\text{Cl} f(\text{Cl} U) \subseteq V$ " (Konstadilaki-Savvopoulou and Jankovic' [1]). If we require the codomain to be almost-regular, the following similar result holds for  $\theta$ -R-continuity.

**THEOREM 9.** Let  $X$  and  $Y$  be topological spaces with  $Y$  almost-regular. Then  $f: X \rightarrow Y$  is  $\theta$ -R-continuous if and only if for each  $x \in X$  and each open subset  $V$  of  $Y$  containing  $f(x)$ , there exists an open subset  $U$  of  $X$  containing  $x$  such that  $\text{Cl}_\theta f(\text{Cl} U) \subseteq V$ .

PROOF. Assume  $f: X \rightarrow Y$  is  $\theta$ -R-continuous. Let  $x \in X$  and let  $V$  be an open subset of  $Y$  containing  $f(x)$ . Then there exists an open subset  $U$  of  $X$  containing  $x$  such that  $\text{Cl}_\theta f(U) \subseteq V$ . Since  $f$  is continuous,  $\text{Cl}_\theta f(\text{Cl} U) \subseteq \text{Cl}_\theta \text{Cl} f(U) \subseteq \text{Cl}_\theta \text{Cl}_\theta f(U)$  and since  $Y$  is almost-regular,  $\text{Cl}_\theta \text{Cl}_\theta f(U) = \text{Cl}_\theta f(U) \subseteq V$ . Thus  $\text{Cl}_\theta f(\text{Cl} U) \subseteq V$ .

The converse implication is immediate.  $\square$

In Konstadilaki-Savvopoulou and Jankovic' [1] the range of an R-continuous function is shown to be  $R_0$ . Here we show that the range of a  $\theta$ -R-continuous function satisfies the stronger  $R_1$  condition. The following definition is implicit in Theorem 3.1 in Jankovic' [7].

**DEFINITION 8.** Jankovic' [7]. A space  $X$  is  $R_1$  if for each open set  $U$  and each  $x \in U$ ,  $\text{Cl}_\theta \{x\} \subseteq U$ .

**THEOREM 10.** If  $f: X \rightarrow Y$  is a  $\theta$ -R-continuous surjection, then  $Y$  is  $R_1$ .

PROOF. Let  $y \in Y$  and let  $V$  be an open subset of  $Y$  containing  $y$ . Let  $x \in X$  such that  $y = f(x)$ . Since  $f$  is  $\theta$ -R-continuous, there exists an open subset  $U$  of  $X$  containing  $x$  for which  $\text{Cl}_\theta f(U) \subseteq V$ . Then  $\text{Cl}_\theta \{y\} \subseteq \text{Cl}_\theta f(U) \subseteq V$ .  $\square$

We close this section with a sample of the basic properties of  $\theta$ -R-continuous functions concerning composition and restriction. Most of these are analogues of the corresponding properties for R-continuous or continuous functions. The proofs are straightforward and are omitted.

**THEOREM 11.** If  $f: X \rightarrow Y$  is continuous and  $g: Y \rightarrow Z$  is  $\theta$ -R-continuous, then  $g \circ f: X \rightarrow Z$  is  $\theta$ -R-continuous.

**COROLLARY 1.** If both  $f: X \rightarrow Y$  and  $g: Y \rightarrow Z$  are  $\theta$ -R-continuous, then  $g \circ f: X \rightarrow Z$  is  $\theta$ -R-continuous.

THEOREM 12. If  $f: X \rightarrow Y$  and  $g: Y \rightarrow Z$  are functions with  $g \circ f: X \rightarrow Z$   $\theta$ -R-continuous, and  $f$  is an open surjection, then  $g$  is  $\theta$ -R-continuous

THEOREM 13. If  $f: X \rightarrow Y$  is  $\theta$ -R-continuous,  $A \subseteq X$ , and  $f(A) \subseteq B \subseteq Y$ , then  $f|_A: A \rightarrow B$  is  $\theta$ -R-continuous.
