We present a Lie algebraic technique for the valuation of multi-asset financial derivatives with time-dependent parameters. Exploiting the dynamical symmetry of the pricing partial differential equations of the financial derivatives, the new method enables us to derive analytical closed-form pricing formulae very straightforwardly. We believe that this new approach will provide an efficient and easy-to-use method for the valuation of financial derivatives.

2000 Mathematics Subject Classification: 91B28, 70G65, 35K15.

1. Introduction. The Lie algebraic method is introduced by Lo and Hui [8] to the field of finance for the pricing of single-asset financial derivatives with time-dependent model parameters. This new method is based upon the Wei-Norman theorem (Wei and Norman [12]) and has never been used in the field of finance. It is very simple and has been successfully applied to tackle time-dependent Schrödinger equation associated with generalized quantum time-dependent oscillators (Lo [2, 3], Ng and Lo [10], and Lo and Wong [9]) as well as the Fokker-Planck equation (Lo [4, 5, 6, 7]). Exploiting the well-defined algebraic structures of the pricing partial differential equations, analytical closed-form pricing formulae can be derived for financial derivatives with time-dependent parameters. For demonstration, we have applied the Lie algebraic approach to value European options for the constant elasticity of variance (CEV) process and corporate discount bonds with default risk. In this paper, we will extend the Lie algebraic approach to the valuation of financial derivatives involving multi-assets and stochastic interest rate, for example, multi-asset options with and without stochastic short-term interest rate. In the valuation of these financial derivatives, the value of each of the underlying assets is assumed to follow the usual lognormal diffusion process

\[
\frac{dS_i}{S_i} = \mu_i(t)dt + \sigma_i(t)dZ_i, \quad 1 \leq i \leq N, \quad (1.1)
\]

where \(\mu_i(t)\) and \(\sigma_i(t)\) are the drift and volatility of the value of asset \(i\), respectively. The dynamics of the short-term interest rate \(r\) is drawn from the term structure model (Vasicek [11])

\[
\frac{dr}{r} = \kappa(t)[\theta(t) - r]dt + \sigma_r(t)dZ_r, \quad (1.2)
\]
where the short-term interest rate is mean-reverting to long-term mean \( \theta(t) \) at speed \( \kappa(t) \) and \( \sigma_r(t) \) is the volatility of \( r \). The Wiener processes \( dZ_r \) and \( dZ_i \) are correlated with
\[
dZ_idZ_r = \rho_{ir}(t)dt, \quad dZ_idZ_j = \rho_{ij}(t)dt, \tag{1.3}
\]
where \( \rho_{ir}(t) \) and \( \rho_{ij}(t) \) are the correlation coefficients, and we must necessarily have \( \rho_{rr}(t) = \rho_{ii}(t) = 1 \), \(-1 < \rho_{ir}(t) = \rho_{ri}(t) < 1 \), and \(-1 < \rho_{ij}(t) = \rho_{ji}(t) < 1 \) for \( 1 \leq i, j \leq N \). It has been pointed out that such a pricing problem is rather formidable and defies the conventional approach for the single-asset Black-Scholes model with time-dependent parameters (Bos and Ware [1]). Nevertheless, within the framework of the Lie algebraic approach, the generalization is very simple and straightforward.

This paper is organized as follows. Section 2 outlines the Wei-Norman theorem and its applications. Section 3 applies the Lie algebraic technique to the valuation problem of multi-asset options in which the short-term interest rate is not treated as a stochastic variable. Section 4 studies the pricing of multi-asset options with stochastic short-term interest rate using the new valuation approach. Finally, Section 5 briefly summaries and concludes the paper.

2. Wei-Norman theorem. Consider the linear operator differential equation of the first order
\[
\frac{dU(t)}{dt} = H(t)U(t); \quad U(0) = 1, \tag{2.1}
\]
where \( H \) and \( U \) are both time-dependent linear operators in a Banach space or a finite-dimensional space. According to the Wei-Norman theorem (Wei and Norman [12]), if the operator \( H \) can be expressed as
\[
H(t) = \sum_{n=1}^{N} a_n(t)L_n, \tag{2.2}
\]
where \( a_n \)'s are scalar functions of time and \( L_n \) are the generators of an \( N \)-dimensional solvable Lie algebra or the real split 3-dimensional simple Lie algebra, then the operator \( U \) can be expressed as
\[
U(t) = \prod_{n=1}^{N} \exp \left[ g_n(t)L_n \right]. \tag{2.3}
\]
Here the \( g_n \)'s are time-dependent scalar functions to be determined. To find the \( g_n \)'s, we simply substitute (2.2) and (2.3) into (2.1) and compare the two sides term by term to obtain a set of coupled nonlinear differential equations
\[
\frac{dg_n(t)}{dt} = \sum_{m=1}^{N} \eta_{nm}a_m(t), \quad g_n(0) = 0, \tag{2.4}
\]
where \( \eta_{nm} \) are nonlinear functions of \( g_n \)'s. Thus, we have reduced the linear operator differential equation (2.1) to a set of coupled nonlinear differential equations of scalar functions (2.4).
For illustration, we consider the special case that the generators $L_n$’s form the Heisenberg-Weyl Lie algebra defined by the commutation relations

$$[L_1, L_2] = L_3, \quad [L_1, L_3] = [L_2, L_3] = 0.$$  \hspace{1cm} (2.5)

Then, $H$ is given by

$$H(t) = a_1(t)L_1 + a_2(t)L_2 + a_3(t)L_3.$$  \hspace{1cm} (2.6)

According to the Wei-Norman theorem, $U(t)$ can be expressed as

$$U(t) = \exp [g_1(t)L_1] \cdot \exp [g_2(t)L_2] \cdot \exp [g_3(t)L_3].$$  \hspace{1cm} (2.7)

By differentiation, we obtain

$$\frac{dU(t)}{dt} U(t)^{-1} = \frac{dg_1(t)}{dt} L_1 + \frac{dg_2(t)}{dt} \exp [g_1(t)L_1] L_2 \exp [-g_1(t)L_1] + \frac{dg_3(t)}{dt} \exp [g_1(t)L_1] \exp [g_2(t)L_2] L_3 \exp [-g_2(t)L_2] \exp [-g_1(t)L_1]$$

$$= \frac{dg_1(t)}{dt} L_1 + \frac{dg_2(t)}{dt} L_2 + \left[ \frac{dg_3(t)}{dt} + g_1(t) \frac{dg_2(t)}{dt} \right] L_3.$$  \hspace{1cm} (2.8)

Comparing (2.6) and (2.8) yields a set of three coupled nonlinear differential equations

$$\frac{dg_1(t)}{dt} = a_1(t), \quad \frac{dg_2(t)}{dt} = a_2(t),$$

$$\frac{dg_3(t)}{dt} + g_1(t) \frac{dg_2(t)}{dt} = a_3(t).$$  \hspace{1cm} (2.9)

It is not difficult to show that the set of differential equations can be easily solved by quadrature

$$g_1(t) = \int_0^t d\tau a_1(\tau),$$

$$g_2(t) = \int_0^t d\tau a_2(\tau),$$

$$g_3(t) = \int_0^t d\tau [a_3(\tau) - a_2(\tau)g_1(\tau)].$$  \hspace{1cm} (2.10)

As a result, the operator $U(t)$ is thus determined.

3. Multi-asset European options. The fair price $P(S_1, S_2, \ldots, S_n, t)$ of a multi-asset European option with time-dependent parameters can be determined by solving the multi-asset generalization of the Black-Scholes equation

$$\frac{\partial P}{\partial t} = \frac{1}{2} \sum_{i,j=1}^n \sigma_i(t)\sigma_j(t)\rho_{ij}(t)S_iS_j \frac{\partial^2 P}{\partial S_i \partial S_j} + \sum_{i=1}^n [r(t) - d_i(t)]S_i \frac{\partial P}{\partial S_i} - r(t)P,$$  \hspace{1cm} (3.1)
where \( t \) is the time to maturity. Introducing the new variables \( x_i = \ln(S_i) \), the pricing equation is simplified to

\[
\frac{\partial P}{\partial t} = \frac{1}{2} \sum_{i,j=1}^{n} \sigma_i(t) \sigma_j(t) \rho_{ij}(t) \frac{\partial^2 P}{\partial x_i \partial x_j} + \sum_{i=1}^{n} \left[ r(t) - d_i(t) - \frac{\sigma_i(t)^2}{2} \right] \frac{\partial P}{\partial x_i} - r(t)P
\]

\[
\equiv [H(t) - r(t)]P. \tag{3.2}
\]

It is obvious that the operator \( H(t) \) can be rewritten as follows:

\[
H(t) = \sum_{i,j=1}^{n} A_{ij}(t) \hat{L}_{ij} + \sum_{i=1}^{n} B_i(t) \hat{D}_i, \tag{3.3}
\]

where

\[
\hat{L}_{ij} = \frac{\partial^2}{\partial x_i \partial x_j}, \quad \hat{D}_i = \frac{\partial}{\partial x_i},
\]

\[
A_{ij}(t) = \frac{1}{2} \sigma_i(t) \sigma_j(t) \rho_{ij}(t), \quad B_i(t) = r(t) - d_i(t) - \frac{\sigma_i^2}{2}. \tag{3.4}
\]

The operators \( L_{ij} \) and \( D_i \) form a solvable algebra; in fact, they all commute. We may now define the evolution operator \( U(t,0) \) such that

\[
P(x_1, x_2, \ldots, x_n, t) = \exp \left[ - \int_0^t r(t') dt' \right] \cdot U(t,0)P(x_1, x_2, \ldots, x_n, 0). \tag{3.5}
\]

Inserting (3.5) into (3.2) yields the evolution equation

\[
\frac{\partial}{\partial t} U(t,0) = H(t)U(t,0), \quad U(0,0) = 1. \tag{3.6}
\]

Since the operators \( L_{ij} \) and \( D_i \) all commute with each other, the Wei-Norman theorem states that the evolution operator \( U(t,0) \) can be expressed in the form (Wei and Norman [12])

\[
U(t,0) = \prod_{i=1}^{n} \exp [b_i(t)\hat{D}_i] \cdot \prod_{i,j=1}^{n} \exp [a_{ij}(t)\hat{L}_{ij}], \tag{3.7}
\]

where the coefficients \( a_{ij}(t) \) and \( b_i(t) \) are simply given by

\[
a_{ij}(t) = \frac{1}{2} \int_0^t \sigma_i(t') \sigma_j(t') \rho_{ij}(t') dt',
\]

\[
b_i(t) = \int_0^t \left[ r(t') - d_i(t') - \frac{\sigma_i(t')^2}{2} \right] dt'. \tag{3.8}
\]

Hence, we have found an exact form of the time evolution operator \( U(t,0) \).
We define $a(t)$ as the $n \times n$ matrix whose elements are given by $a_{ij}(t)$, and $a^{-1}(t)$ as its inverse. Then, it is not difficult to show that

$$P(x_1, x_2, \ldots, x_n, t) = \int_{-\infty}^{\infty} dy_1 \int_{-\infty}^{\infty} dy_2 \cdots \int_{-\infty}^{\infty} dy_n P(y_1, y_2, \ldots, y_n, 0)$$

$$\times K(x_1, x_2, \ldots, x_n, t; y_1, y_2, \ldots, y_n, 0),$$

where

$$K(x_1, x_2, \ldots, x_n, t; y_1, y_2, \ldots, y_n, 0) = \frac{1}{\sqrt{(4\pi)^n \det(a)}} \exp \left[ -\int_0^t r(t') dt' \right]$$

$$\times \exp \left\{ -\frac{1}{4} \sum_{i,j=1}^{n} (x_i - y_i + b_i)(a^{-1})_{ij}(x_j - y_j + b_j) \right\},$$

is the propagator of the pricing equation in (3.2). With $n = 1$, we will recover the well-known result of single-asset option pricing.

4. Multi-asset European options with stochastic interest rate. In the presence of stochastic short-term interest rate, the price $P(S_1, S_2, \ldots, S_n, r, t)$ of a multi-asset European option obeys the partial differential equation

$$\frac{\partial P}{\partial t} = \frac{1}{2} \sum_{i,j=1}^{n} \sigma_i(t) \sigma_j(t) \rho_{ij}(t) S_i S_j \frac{\partial^2 P}{\partial S_i \partial S_j}$$

$$+ \frac{1}{2} \sigma_r(t)^2 \frac{\partial^2 P}{\partial r^2} + \sum_{i=1}^{n} \sigma_i(t) \sigma_r(t) \rho_{ir}(t) S_i \frac{\partial^2 P}{\partial S_i \partial r}$$

$$+ \sum_{i=1}^{n} \left[ r - d_i(t) \right] S_i \frac{\partial P}{\partial S_i} + \kappa(t) \left[ \theta(t) - r \right] \frac{\partial P}{\partial r} - rP$$

$$= \frac{1}{2} \sum_{i,j=1}^{n} \sigma_i(t) \sigma_j(t) \rho_{ij}(t) \frac{\partial^2 P}{\partial x_i \partial x_j}$$

$$+ \frac{1}{2} \sigma_r(t)^2 \frac{\partial^2 P}{\partial r^2} + \sum_{i=1}^{n} \sigma_i(t) \sigma_r(t) \rho_{ir}(t) \frac{\partial^2 P}{\partial x_i \partial r}$$

$$+ \sum_{i=1}^{n} \left[ r - d_i(t) - \frac{1}{2} \sigma_i(t)^2 \right] \frac{\partial P}{\partial x_i} + \kappa(t) \left[ \theta(t) - r \right] \frac{\partial P}{\partial r} - rP,$$

where $x_i = \ln(S_i)$ and $t$ is the time to maturity. To solve this partial differential equation, we first define the evolution operator $U(t, 0) \equiv U_0(t, 0) U_I(t, 0)$ such that

$$P(x_1, x_2, \ldots, x_n, r, t) = U(t, 0) P(x_1, x_2, \ldots, x_n, r, 0)$$

$$= U_0(t, 0) U_I(t, 0) P(x_1, x_2, \ldots, x_n, r, 0).$$

Inserting (4.2) into (4.1) yields the evolution equations

$$H_0(t) U_0(t, 0) = \frac{\partial}{\partial t} U_0(t, 0), \quad U_0(0, 0) = 1,$$

$$H_I(t) U_I(t, 0) = \frac{\partial}{\partial t} U_I(t, 0), \quad U_I(0, 0) = 1,$$
where

\[
H_0(t) = \frac{1}{2} \sum_{i,j=1}^{n} \sigma_i(t) \sigma_j(t) \rho_{ij}(t) \frac{\partial^2}{\partial x_i \partial x_j} + \frac{1}{2} \sigma_r(t)^2 \frac{\partial^2}{\partial r^2} + \sum_{i=1}^{n} \sigma_i(t) \sigma_r(t) \rho_{ir}(t) \frac{\partial^2}{\partial x_i \partial r} + \sum_{i=1}^{n} \rho_{ir}(t) r \frac{\partial}{\partial x_i} - \kappa(t) r \frac{\partial}{\partial r} \tag{4.5}
\]

and \(H_I \equiv U_0(t,0)^{-1}[H(t) - H_0(t)]U_0(t,0)\). It is not difficult to show that the operator \(H_0(t)\) can be rewritten in the following form:

\[
H_0(t) = \sum_{i,j=1}^{n} A_{ij}(t) \hat{L}_{ij} + \sum_{i=1}^{n} E_i(t) \hat{D}_i + \sum_{i=1}^{n} F_i(t) \hat{M}_i + B_1 \hat{J}_1 + B_2 \hat{J}_2, \tag{4.6}
\]

where

\[
\hat{L}_{ij} = \frac{\partial^2}{\partial x_i \partial x_j}, \quad \hat{D}_i = r \frac{\partial}{\partial x_i}, \quad \hat{M}_i = \frac{\partial^2}{\partial x_i \partial r}, \quad \hat{J}_2 = \frac{\partial^2}{\partial r^2}, \quad \hat{J}_1 = r \frac{\partial}{\partial r}, \quad \hat{J}_3 = \frac{\partial^2}{\partial r^2}, \quad \hat{J}_1 = r \frac{\partial}{\partial r}, \quad \hat{J}_2 = \frac{\partial^2}{\partial r^2}
\]

\[
A_{ij}(t) = \frac{1}{2} \sigma_i(t) \sigma_j(t) \rho_{ij}(t), \quad B_1(t) = -\kappa(t), \quad B_2(t) = \frac{1}{2} \sigma_r(t)^2, \quad E_i(t) = 1, \quad F_i(t) = \sigma_i(t) \sigma_r(t) \rho_{ir}(t). \tag{4.7}
\]

The operators \(\hat{L}_{ij}, \hat{D}_i, \hat{M}_i, \) and \(\hat{J}_i\) form a solvable Lie algebra

\[
[\hat{L}_{ij}, \hat{L}_{kl}] = [\hat{L}_{ij}, \hat{D}_k] = [\hat{L}_{ij}, \hat{M}_k] = [\hat{L}_{ij}, \hat{J}_1] = [\hat{L}_{ij}, \hat{J}_2] = [\hat{M}_i, \hat{J}_2] = 0,
\]

\[
[\hat{D}_i, \hat{M}_j] = -\hat{L}_{ij}, \quad [\hat{D}_i, \hat{J}_1] = -\hat{D}_i, \quad [\hat{D}_i, \hat{J}_2] = -2 \hat{M}_i, \quad [\hat{M}_i, \hat{J}_1] = \hat{M}_i, \quad [\hat{J}_1, \hat{J}_2] = -2 \hat{J}_2, \tag{4.8}
\]

where \(i, j, k, l = 1, 2, \ldots, n\). According to the Wei-Norman theorem (Wei and Norman [12]), the evolution operator \(U_0(t,0)\) can be expressed in the form

\[
U_0(t,0) = \exp \left[ \sum_{i=1}^{n} b_i(t) \hat{D}_i \right] \exp \left[ \sum_{i,j=1}^{n} a_{ij}(t) \hat{L}_{ij} \right] \exp \left[ c_2(t) \hat{J}_2 \right] \times \exp \left[ \sum_{i=1}^{n} f_i(t) \hat{M}_i \right] \exp \left[ c_1(t) \hat{J}_1 \right], \tag{4.9}
\]

where the coefficients \(a_{ij}(t), c_i(t), b_i(t), \) and \(f_i(t)\) are to be determined. Then, by direct differentiation with respect to \(t\), we obtain

\[
\frac{\partial U_0(t,0)}{\partial t} U_0(t,0)^{-1} = \sum_{i,j=1}^{n} g_{ij}(t) \hat{L}_{ij} + \sum_{i=1}^{n} h_i(t) \hat{D}_i \quad + \sum_{i=1}^{n} p_i(t) \hat{M}_i + q_1(t) \hat{J}_1 + q_2(t) \hat{J}_2 \tag{4.10}
\]
with

\[ g_{ij}(t) = \frac{\partial a_{ij}}{\partial t} - b_j \frac{\partial f_i}{\partial t} + b_i b_j \frac{\partial c_2}{\partial t} + b_j (2c_2 b_i - f_i) \frac{\partial c_1}{\partial t}, \]

\[ h_i(t) = \frac{\partial b_i}{\partial t} - b_i \frac{\partial c_1}{\partial t}, \]  

\[ p_i(t) = \frac{\partial f_i}{\partial t} - 2b_i \frac{\partial c_2}{\partial t} - (4c_2 b_i - f_i) \frac{\partial c_1}{\partial t}, \]

\[ q_1(t) = \frac{\partial c_1}{\partial t}, \quad q_2(t) = \frac{\partial c_2}{\partial t} + 2c_2 \frac{\partial c_1}{\partial t}. \]  

(4.11)

Substituting (4.7), (4.10), and (4.11) into (4.3), and comparing the two sides, we, after simplification, find

\[ c_1(t) = \int_0^t dt' B_1(t'), \]

\[ c_2(t) = \exp[-2c_1(t)] \int_0^t dt' B_2(t') \exp[2c_1(t')], \]

\[ b_i(t) = \exp[c_1(t)] \int_0^t dt' E_i(t') \exp[-c_1(t')], \]

(4.13)

\[ f_i(t) = \exp[-c_1(t)] \int_0^t dt' \{ F_i(t') + 2B_2(t') b_i(t') \} \exp[c_1(t')], \]

\[ a_{ij}(t) = \int_0^t dt' \{ A_{ij}(t') + [F_i(t') + B_2(t') b_i(t')] b_j(t') \}. \]

Once the coefficients \(a_{ij}(t), c_i(t), b_i(t),\) and \(f_i(t)\) are known, the operator \(U_0(t,0)\) is uniquely determined.

Next, using the above explicit form of the operator \(U_0(t,0)\), we can obtain the exact form of the operator \(H_I(t)\)

\[ H_I(t) = \sum_{i=1}^n \left\{ f_i(t) + \kappa(t) \theta(t) b_i(t) - \left[ d_i(t) + \frac{1}{2} \sigma_i(t)^2 \right] \right\} \frac{\partial}{\partial x_I} \]

\[ + \{ \kappa(t) \theta(t) + 2c_2(t) \} \exp[c_1(t)] \frac{\partial}{\partial r} - r \exp[-c_1(t)]. \]  

(4.14)

It is easy to see that the operator \(U_I(t,0)\) can be expressed in the form

\[ U_I(t,0) = \exp\left[ \sum_{i=1}^n \xi_i(t) \frac{\partial}{\partial x_I} \right] \mathcal{U}(t,0), \]  

(4.15)

where

\[ \xi_i(t) = \int_0^t dt' \left\{ f_i(t') + \kappa(t') \theta(t') b_i(t') - \left[ d_i(t') + \frac{1}{2} \sigma_i(t')^2 \right] \right\} \]  

(4.16)

and \(\mathcal{U}(t,0)\) satisfies the evolution equation

\[ \mathcal{H}(t) \mathcal{U}(t,0) = \sum_{i=1}^3 \eta_i(t) \hat{e}_i \mathcal{U}(t,0) = \frac{\partial}{\partial t} \mathcal{U}(t,0), \quad \mathcal{U}(0,0) = 1 \]  

(4.17)
with
\[ \eta_1(t) = \left[ \kappa(t) \vartheta(t) + 2c_2(t) \right] \exp \left[ c_1(t) \right], \]
\[ \eta_2(t) = - \exp \left[ -c_1(t) \right], \quad \eta_3(t) = 0, \] (4.18)
\[ \hat{e}_1 = \frac{\partial}{\partial r}, \quad \hat{e}_2 = r, \quad \hat{e}_3 = 1. \]

The operators \( \hat{e}_i \) form the Heisenberg-Weyl Lie algebra
\[ [\hat{e}_1, \hat{e}_2] = \hat{e}_3, \quad [\hat{e}_1, \hat{e}_3] = [\hat{e}_2, \hat{e}_3] = 0. \] (4.19)

Following a similar procedure as shown above, the operator \( \hat{u}(t,0) \) is found to be
\[ \hat{u}(t,0) = \exp \left[ \mu_2(t) \hat{e}_2 \right] \exp \left[ \mu_1(t) \hat{e}_1 \right] \exp \left[ \mu_3(t) \hat{e}_3 \right] \] (4.20)
with
\[ \mu_1(t) = \int_0^t \exp \left[ \eta_1(t') \right], \quad \mu_2(t) = \int_0^t \exp \left[ \eta_2(t') \right], \quad \mu_3(t) = \int_0^t \exp \left[ \eta_3(t') \right]. \] (4.21)

As a result, we have obtained the exact form of the desired time evolution operator \( U(t,0) \) of the pricing equation in (4.1). It is then straightforward to show that
\[ P(x_1, x_2, \ldots, x_n, r, t) \] is given by
\[ \int_0^\infty \int_0^\infty \cdots \int_0^\infty \exp \left\{ -\frac{1}{4} \sum_{i,j=1}^n (x_i - y_i + u_i)(a^{-1})_{ij}(x_j - y_j + v_j) \right\} \] (4.22)
\[ \times \exp \left[ \frac{1}{\sqrt{(4\pi)^n \det(a)}} \exp \left[ \mu_3(t) + c_2(t) \mu_2(t)^2 \exp \left[ 2c_1(t) \right] + \mu_2(t) \exp \left[ c_1(t) \right] \right] \right] \]
\[ \times K(x_1, x_2, \ldots, x_n, t; y_1, y_2, \ldots, y_n, 0; r), \]
\[ = \frac{Q(r,t)}{\sqrt{(4\pi)^n \det(a)}} \exp \left\{ -\frac{1}{4} \sum_{i,j=1}^n (x_i - y_i + u_i)(a^{-1})_{ij}(x_j - y_j + v_j) \right\} \] (4.23)
is the propagator of the pricing equation in (4.1) and
\[ \nu_i(t) = b_i(t) r + \xi_i(t) + \mu_2(t) f_i(t) \exp \left[ c_1(t) \right]. \] (4.24)

The matrix \( a(t) \) is the \( n \times n \) matrix whose elements are given by \( a_{ij}(t) \), and \( a^{-1}(t) \) is its inverse. Furthermore, in terms of the riskless bond function \( Q(r,t) \) of the Vasicek model with explicitly time-dependent parameters, we can easily rewrite the propagator \( K(x_1, x_2, \ldots, x_n, t; y_1, y_2, \ldots, y_n, 0; r) \) and \( \nu_i(t) \) as follows:
\[ K(x_1, x_2, \ldots, x_n, t; y_1, y_2, \ldots, y_n, 0; r) \]
\[ = \frac{Q(r,t)}{\sqrt{(4\pi)^n \det(a)}} \exp \left\{ -\frac{1}{4} \sum_{i,j=1}^n (x_i - y_i + u_i)(a^{-1})_{ij}(x_j - y_j + v_j) \right\} \] (4.25)
and \( \nu_i(t) = -\ln[Q(r,t)] - a_{ii}(t) - \int_0^t dt' d_i(t'). \)
For illustration, we consider the evaluation of a European call option on the maximum of two assets \( S_1 \) and \( S_2 \) with a strike price of \( K \). The payoff at expiry for such an option is \( \max(\max(S_1, S_2) - K, 0) \). Then the option price \( P(S_1, S_2, r, t) \) is given by

\[
P(S_1, S_2, r, t) = I_1 + I_2 + I_3 - KQ(r, t),
\]

where

\[
I_1 = S_1 N_2(\theta_1, \phi_1, \rho_1) \exp\left(-\int_0^t dt' d_1(t')\right) \frac{1}{\sqrt{1 + \chi_1^2}}
\]

\[
I_2 = S_2 N_2(\theta_2, \phi_2, \rho_2) \exp\left(-\int_0^t dt' d_2(t')\right) \frac{1}{\sqrt{1 + \chi_2^2}}
\]

\[
I_3 = K Q(r, t) N_2(\theta_3, \phi_3, \rho_3)
\]

\[
\chi_1 = \frac{a_{11} - a_{12}}{\sqrt{\det(a)}}
\]

\[
\chi_2 = \frac{a_{22} - a_{12}}{\sqrt{\det(a)}}
\]

\[
\rho_1 = \frac{\chi_1}{\sqrt{1 + \chi_1^2}}
\]

\[
\rho_2 = \frac{\chi_2}{\sqrt{1 + \chi_2^2}}
\]

\[
\rho_3 = \frac{a_{12}}{a_{11} a_{22}}
\]

\[
\theta_1 = -\sqrt{\frac{(1 - \rho_1^2)(a_{11} - 2a_{12} + a_{22})}{2 \cdot \det(a)}} \cdot \left\{ \ln\left(\frac{KQ}{S_1}\right) - a_{11} + \int_0^t dt' d_1(t') \right\}
\]

\[
\phi_1 = \sqrt{\frac{(1 - \rho_1^2)a_{11}}{2 \cdot \det(a)}} \cdot \left\{ \ln\left(\frac{S_1}{S_2}\right) + a_{11} - 2a_{12} + a_{22} - \int_0^t dt' d_1(t') + \int_0^t dt' d_2(t') \right\}
\]

\[
\theta_2 = -\sqrt{\frac{(1 - \rho_2^2)(a_{11} - 2a_{12} + a_{22})}{2 \cdot \det(a)}} \cdot \left\{ \ln\left(\frac{KQ}{S_2}\right) - a_{22} + \int_0^t dt' d_2(t') \right\}
\]

\[
\phi_2 = \sqrt{\frac{(1 - \rho_2^2)a_{22}}{2 \cdot \det(a)}} \cdot \left\{ \ln\left(\frac{S_2}{S_1}\right) + a_{11} - 2a_{12} + a_{22} - \int_0^t dt' d_2(t') + \int_0^t dt' d_1(t') \right\}
\]

\[
\theta_3 = \frac{\ln(KQ/S_1) + a_{11} + \int_0^t dt' d_1(t')}{\sqrt{2}a_{11}}
\]

\[
\phi_3 = \frac{\ln(KQ/S_2) + a_{22} + \int_0^t dt' d_2(t')}{\sqrt{2}a_{22}}
\]

Here, \( N_2(\theta, \phi, \rho) \) stands for the bivariate cumulative normal density function. It should be noted that, by setting \( \sigma_r(t) = \rho_{1r}(t) = \rho_{2r}(t) = \kappa(t) = 0 \) in the above price function, we will obtain the option price \( P(S_1, S_2, t) \) for the special case with nonstochastic short-term interest rate. Furthermore, as far as we know, the results in (4.26) and (4.27) are completely new.
5. Conclusion. In this paper, we apply the Lie algebraic approach to valuation of multi-asset financial derivatives with time-dependent parameters. Based upon the dynamical symmetry of the pricing partial differential equations of the financial derivatives, the method is able to derive analytical closed-form pricing formulae very straightforwardly. We believe that the new approach will provide an efficient and easy-to-use method for the valuation of financial derivatives. Furthermore, this simple Lie algebraic approach can be easily extended to other financial derivatives with well-defined algebraic structures.

Special Issue on
Boundary Value Problems on Time Scales

Call for Papers

The study of dynamic equations on a time scale goes back to its founder Stefan Hilger (1988), and is a new area of still fairly theoretical exploration in mathematics. Motivating the subject is the notion that dynamic equations on time scales can build bridges between continuous and discrete mathematics; moreover, it often reveals the reasons for the discrepancies between two theories.

In recent years, the study of dynamic equations has led to several important applications, for example, in the study of insect population models, neural network, heat transfer, and epidemic models. This special issue will contain new researches and survey articles on Boundary Value Problems on Time Scales. In particular, it will focus on the following topics:

- Existence, uniqueness, and multiplicity of solutions
- Comparison principles
- Variational methods
- Mathematical models
- Biological and medical applications
- Numerical and simulation applications

Before submission authors should carefully read over the journal’s Author Guidelines, which are located at http://www.hindawi.com/journals/ade/guidelines.html. Authors should follow the Advances in Difference Equations manuscript format described at the journal site http://www.hindawi.com/journals/ade/. Articles published in this Special Issue shall be subject to a reduced Article Processing Charge of €200 per article. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:

<table>
