Transfer and complex oriented cohomology rings

Malkhaz Bakuradze
Stewart Priddy

Abstract
For finite coverings we elucidate the interaction between transferred Chern classes and Chern classes of transferred bundles. This involves computing the ring structure for the complex oriented cohomology of various homotopy orbit spaces. In turn these results provide universal examples for computing the stable Euler classes (i.e. $\text{Tr} (1)$) and transferred Chern classes for $p$-fold covers. Applications to the classifying spaces of $p$-groups are given.

AMS Classification 55N22; 55R12

Keywords Transfer, Chern class, classifying space, complex cobordism, Morava K-theory

1 Introduction

For various examples of finite groups the complex oriented cohomology ring coincides with its subring generated by Chern classes [21],[22],[24]. Even more groups are good in the sense that their Morava K-theory is generated by transferred Chern classes of complex representations of subgroups [10]. Special effort was needed to find an example of a group not good in this sense [14]. Thus the relations in the complex oriented cohomology ring of a finite group derived from formal properties of the transfer should play a major role. The purpose of this paper is to elucidate for finite coverings the interaction between transferred Chern classes and Chern classes of transferred bundles.

Let $p$ be a prime and let $G_p$ be a subgroup of the symmetric group. In this paper we consider the complex oriented cohomology of homotopy orbit spaces $X_{pG}^p = E \text{G} \text{G}^p X^p$. Several authors have computed these cohomology groups, [15], [11], [12], [10], however we are particularly interested in the ring structure and thereby explicit formulas for the transfer. Thus we are led to consider Fibrins reciprocity, the relation between cup products and transfer:

$$\text{Tr} (x)y = \text{Tr} (x \cdot y)$$
(formula (i) of Section 2) where \( E \to X \) is the covering projection and
\[
\text{Tr} : E (X^p) \to E (X_{RG}^p)
\]
is the associated transfer homomorphism.

Let \( p \) be the subgroup of cyclic permutations of order \( p \). Our results for \( MU (X_{hG}^p) \), \( X = \mathbb{C}P^1 \), and \( \mathbb{C}P^1 \) the canonical complex line bundle, provide a universal example which enables us to write explicitly the Chern classes \( c_1, \ldots, c_{p-1} \) of the transferred bundle as certain formal power series in the Euler class \( c_p(X) \) with coefficients in \( E(B) \) plus certain transferred classes of the bundle \( X \). In Section 3 we give an algorithm for computing these coefficients.

In particular for \( E = BP \), Brown-Peterson cohomology, the coefficients of this formal power series are invariant under the action of the normalizer of \( \mathbb{F}_p \) in \( p \). This enables us to give the similar results for \( p \) coverings. Moreover in Section 4 we compute the algebra \( BP (X_{hG}^p) \) and show that its multiplicative structure is completely determined by Frobenius reciprocity.

In addition for \( E = K(s) \), Morava \( K \)-theory, the computations become easier: we show in Section 5 that the formal power series in the algorithm above descend to polynomials. We derive an alternative way for calculation and give some examples.

Section 6 is devoted to extending some results of [10] in Morava \( K \)-theory. In particular we show that if \( X \) is good then \( X_{hG}^p \) is good.

In Section 7 we give some applications to classifying spaces of finite groups.

We would like to thank several people for their help during the course of this work: D. Ravenel for supplying us with the proof of Lemma 5.3, M. Jibladze for some Maple programs used in the examples of Section 5, and finally the referee who suggested many improvements.

The first author was supported by CRDF grant GM1 2083 and by the Max-Planck-Institut für Mathematik.

A word about notation: in Sections 2, 3, 4 and 7 we denote \( \mathbb{C}P^1 \) simply by \( X \).

## 2 Preliminaries

We recall that a multiplicative cohomology theory \( E \) is called complex oriented if there exists a Thom class, that is, a class \( u \in E^2(\mathbb{C}P^1) \) that restricts to a
generator of the free one-dimensional \(E\) module \(E^2(\mathbb{C}P^1)\). The universal example is complex cobordism \(MU\). Then
\[
E(\mathbb{C}P^1) = E[[x]];
\]
where \(x\) is the Euler class of the canonical complex line bundle over \(\mathbb{C}P^1 = BU(1)\). Further
\[
E(BU(1)^p) = E[[x_1; \ldots; x_p]];
\]
where \(x_i = c_1(i)\) and \(i\) is the pullback bundle over \(BU(1)^p\) by the projection \(BU(1)^p \to BU(1)\) on the \(i\)-th factor.

Much of our paper is written in terms of transfer maps [1, 13] and formal group laws. Let us give a brief review of formal properties of the transfer. For a finite covering
\[
:X \to X/G
\]
there is a stable transfer map
\[
\text{Tr} = \text{Tr}( ) : X \to X^+ \to X^+;
\]
For any multiplicative cohomology theory \(E\), Frobenius reciprocity holds i.e., the induced map \(\text{Tr}\) is a map of \(E(X=G)\) modules
(i) \(\text{Tr}(x \cdot (y)) = \text{Tr}(x)y; x \in \pi E(X); y \in \pi E(X=G)\):
For example
(ii) \(\text{Tr}(1(y)) = \text{Tr}(1)y;\)
The element \(\text{Tr}(1) \in \pi 0(X=G)\) is called the index or stable Euler class of the covering. The following additional properties of the transfer will be used:
(iii) The transfer is natural with respect to pullbacks;
(iv) \(\text{Tr}(1 \cdot 2) = \text{Tr}(1) \cdot \text{Tr}(2)\);
(v) If \(e = 2_1\), then \(\text{Tr}(1) = \text{Tr}(2) \cdot \text{Tr}(1)\).
More generally for a covering projection
\[
H:G : X ! X=G
\]
with \(H\) \(G\) there is a stable transfer map
\[
\text{Tr}_{H,G} : X \to X^+ ; X \to H^+;\]
To ease notation if \(H = e\), as above, we write projection and transfer in equivalent ways \(G; \text{Tr} = \text{Tr}( ) = \text{Tr}_G\).
The reverse composition to (ii) is given by:
(vi) (Double coset formula) If \( K;H \) \( \leq G \) then
\[
K;G \text{Tr}_{H;G} = \sum_{x \in K \setminus H \setminus K} x^{-1} \text{Tr}_{K \setminus H;K} x
\]
where the sum is taken over a set of double coset representatives \( x \in K \cap \langle H \rangle \).

Here \( H \setminus x = xH^{-1} \).

For a regular covering \( H;G \), i.e. \( H \leq G \),
\[
H;G \text{Tr}_{H;G}(x) = N(x) = \sum_{g \in G \setminus H} g(x);
\]
where \( N(x) \) is called the norm or trace of \( x \).

In subsequent sections the reduced transfer \( \text{Tr}_{H;G} : X = G \setminus X = H \) is used.

We recall Quillen's formula [16, 6]. First,
\[
E(B \mathbb{Z};p) = E([z] = ([p](z)));
\]
where \( x \) is the Euler class of a faithful one-dimensional complex representation of \( \mathbb{Z} = p \) and \([p](z)\) is the \( p \)-series or \( p \)-fold iterated formal sum. Then
\[
\text{Tr}_{\mathbb{Z};p}(1) = [p](z)z;
\]
where \( \text{Tr}_{\mathbb{Z};p} \) is the transfer homomorphism for the universal \( \mathbb{Z} = p \)-covering \( E\mathbb{Z};p \) \( \to B \mathbb{Z};p \). The relation \([p](z) = 0\) is equivalent to the transfer relation \([p](z) = 0\) obtained by applying (ii). Of course since the transfer is natural, Quillen's formula enables us to compute the stable Euler class for any regular \( \mathbb{Z} = p \) covering.

In this spirit, let
\[
\mathfrak{t}_p = \{ \mathfrak{t} \in \mathbb{Z}_p \text{ cyclic permutations of order } p \}
\]
be the subgroup of cyclic permutations of order \( p \). For a given free action of \( \mathfrak{t}_p \) on a space \( Y \) with a given complex line bundle \( \mathcal{L} \) we have an equivariant map
\[
\mathfrak{t}_p \times Y \to Y \to X = BU(1)^p;
\]
where \( g \) classifies the line bundle \( t^{i-1} \).

So by naturality of the transfer, the computation of transferred Chern classes \( \text{Tr}(c_i(Y)) \) for cyclic coverings can be reduced to the covering
\[
E(BU(1))^p \to E(BU(1))^p;
\]
as the universal example.
Similarly for the symmetric group.

Let \( E \) be the canonical complex line bundle over \( \mathbb{C}P^1 = BU(1) \) and \( i \) be the pullback bundle over \( BU(1)^p \) by the projection on the \( i \)-th factor as before. Then \( MU(BU(1)^p) = MU(\left[ x_1; \ldots ; x_p \right]) \), \( x_i = c_1(i) \) and \( x_1 \ldots x_p \) is the Euler class of the bundle \( \left[ x_i \right] \).

Note that by transfer property (v), Tr( ) has the same value on the Chern classes \( x_1; \ldots ; x_p \): the group permutes the \( x_i \) and \( t = t_1, t_2 \). Thus in computations of the transfer we sometimes write these Chern classes in an equivalent way \( x; tx; \ldots ; t^{p-1}x \).

For the sphere bundle \( S(\mathbb{C}P^1) \); one has

\[
MU(S(\mathbb{C}P^1)) = MU(\left[ x_1; \ldots ; x_p \right]) = (x_1 \ldots x_p); \tag{2}
\]

Then for the trace map

\[
N = 1 + t + \ldots + t^{p-1}
\]

we have \( \ker N = \text{Im}(1 - t) \), \( t_2 \) in \( MU(BU(1)^p) \) and after restricting \( N \) to \( MU(S(\mathbb{C}P^1)) \) we have the exact sequence

\[
MU(S(\mathbb{C}P^1)) \xrightarrow{N} MU(S(\mathbb{C}P^1)) \xrightarrow{1-t} MU(S(\mathbb{C}P^1)) \xrightarrow{N} MU(S(\mathbb{C}P^1)) \tag{3}
\]

Then let \( E \) be the Atiyah transfer bundle \([2]\),

\[
S(\mathbb{C}P^1) = E \quad S(\mathbb{C}P^1) \tag{4}
\]

be its sphere bundle and

\[
D(\mathbb{C}P^1) = E \quad D(\mathbb{C}P^1) \tag{5}
\]

be its disk bundle. Let \( X = \mathbb{C}P^1 \) then \( D(\mathbb{C}P^1) \) is homotopy equivalent to \( X^p \mathbb{C} = B(oU(1)). \)

The co-orientation \( D(\mathbb{C}P^1) = S(\mathbb{C}P^1) \) gives a long exact sequence

\[
MU(S(\mathbb{C}P^1)) \quad MU(X^p \mathbb{C}) \quad c_p MU((X^p \mathbb{C})) \tag{6}
\]

where \( (X^p \mathbb{C}) \) is the Thom space of the bundle \( X^p \mathbb{C} \) and the right homomorphism is multiplication by the Euler class \( c_p = c_p(\mathbb{C}). \)

Since the diagonal of \( BU(1)^p \) is fixed under the permutation action of \( \mathfrak{S}_p \), the inclusion \( E \to BU(1)^p; x \to (x; \text{fixpoint}) \) defines the inclusions

\[
i: B \to X^p \mathbb{C}
\]

\[
i_0: B \to S(\mathbb{C}P^1);
\]

The projection \( \pi : X^p \to B \) induced by \( \varphi \) defines the projection
\[ \pi_0 : S(1) \to B \] and the compositions \( \pi_0^0, \pi_i \) are the identity. We can consider \( S(1) \) as a bundle over \( B \) with fiber \( S(1^p) \).

Let \( E \) be the canonical line bundle over \( B \) and
\[ = (1^p)^! X^p \]
be the pullback bundle. Thus \( i(1) = 1 \) and \( i(1^p) = C + \ldots + p^{-1} \).

Consider the pullback diagram
\[
\begin{array}{ccc}
E & \to & S^p(1) \\
\downarrow & & \downarrow \\
0 & \to & E \to \text{BU}(1)^p \\
\downarrow & & \downarrow \\
S(1) & \to & X^p 
\end{array}
\]

Let \( Tr = Tr(\varphi) \) be the transfer of the covering \( \varphi \), and \( Tr_0 : S(1) \to S(1^p) \) the transfer map of \( \varphi \).

We will often refer to the following lemma which follows from (3) and Frobenius reciprocity.

**Lemma 2.1** In \( \text{MU}(X^p) \), \( \text{Im} Tr \rightsquigarrow \text{Ker}(\varphi) = 0 \):

**Proof** \( (Tr(1)) = \text{N}(1) = 0 \) a 2 ! \text{Im}(1-t) \) \( Tr(1) = 0 \).

**Remark 2.2** Lemma 2.1 is valid only in complex oriented cohomology \( E \) with torsion free coefficient ring. This lemma is used in the proof of Theorem 3.1 in complex cobordism and in the second statement of Theorem 4.6 in Brown-Peterson cohomology. By naturality, these results hold for all \( E \) in the first case and all \( p \)-local \( E \) in the second.

### 3 Transferred Chern classes for cyclic coverings

In this section we prove our main result for cyclic coverings, Theorem 3.2.

In the notation of the previous section the \( k \)-th Chern class of the bundle \( X^p \) is the elementary symmetric function \( \chi_k(x_1, \ldots, x_p) \) in Chern classes \( x_i \) and
is the sum of \( p \) elementary monomials. The action of \( T \) on the set of these monomials gives us \( p^{-1} \) orbits and the transfer homomorphism is constant on orbits by transfer property (v) or (iii).

Let \( E \) be a complex oriented cohomology theory. For \( k = 1; \ldots; p - 1 \), let

\[ !_k = !_k(x_1; \ldots; x_p) \in E(BU(1)^p) \]

be the sum of representative monomials one from each of these orbits. The value of \( Tr(!_k) \) does not depend on the choice of \( !_k \) since \( !_k \) is defined modulo \( Im(1-t) \) and the transfer homomorphism is zero again by (v). In other words we can take any \( !_k \) for which \( N!_k = !_k(x_1; \ldots; x_p) \) holds. As we shall explain in Corollary 3.6 of Theorem 3.1, the following result enables us to calculate the transfer on all elements whose norm is symmetric.

For ease of notation let \( X = \mathbb{C}P^1 \) and \( c_j = c_j(\ ) \), \( j = 1; \ldots; p \).

**Theorem 3.1** We can construct explicit elements

\[ \begin{array}{c}
^{(k)} \in E^*(BU) ; k = 1; \ldots; p - 1
\end{array} \]

such that

\[ Tr(!_k) = c_k + \sum_{i=0}^{X} (^{(k)}c_p)_i \]

for the transfer of the covering \( : X^p ! X^p_h \).

Before constructing the elements \( _{^{(k)}} \) in Section 3.2 we first prove their existence.

**3.1 Complex cobordism of \( (\mathbb{C}P^1)_h^p \)**

**Theorem 3.2** In \( MU(X^p_h) \)

(a) The annihilator of the Chern class \( c = c_1(\ ) \) coincides with \( ImTr \); 

(b) Multiplication by \( c_0 = c_0(\ ) \) is a monomorphism;

(c) Any element of \( \mathcal{K}er(\ ) \) has the form \( \sum_{k=0}^{p} (^{(k)}c_k)_i \), for some elements \( c_0 \) and \( c_1 \) in \( MU(BU) \).

(d) For \( p = 2 \),

\[ MU(B(oU(1))) = MU[[c;c_1;c_2]]/(c_1 - c_1; c_2 - c_2) \]

\[ = MU(B[[Tr(x); c_2]]/(cTr(x)); x \in MU(BU(1)^2) = MU[[x;tx]]. \]

We need the following lemma.

**Lemma 3.3** The left homomorphism in the long exact sequence (6) is an epimorphism and thus gives a short exact sequence

\[ 0 \to MU(S(p)) \to MU(X^p) \overset{c_p}{\to} MU(X^p) \to 0. \]

Moreover there is a space \( X \) and a stable equivalence

\[ '0 \_ f : S(\ ) \overset{!}{\to} B \_ X ; \]

with \( f \) factoring through the following composite map

\[ S(\ ) \overset{!}{\to} X^p \overset{T}{\to} E \_ BU(1)^p \]

and \( '0 \) as in (7).

**Proof** Consider the Serre spectral sequence for the fibration (7)

\[ S(\ ) \overset{!}{\to} S(\ ) \overset{!}{\to} B : \]

\[ E^{ij}_2 = H^i(S(\ );H^j(S(p);F_q)) \]

with the action of \( H(S(p);F_p) \) on \( H(S(p);F_q) \) by permutations of the cohomological Chern classes.

When \( q = p \), \( E^{0j}_2 = H^j(S(p);F_p) \) and \( E^{10}_2 = H^1(B;F_p) \).

Then in positive dimensions \( H(S(p);F_q) = F_q[x_1,\ldots,x_p]=(x_1\cdots x_p) \) is a permutation representation of \( \text{acting on monomials which have degree zero in at least one indeterminate. This is a free } F_q[\ ]\text{-module since all the monomials that are fixed under this action have been factored out after quotienting by the ideal } (x_1\cdots x_p). \) Hence the cohomology of \( H \) with coefficients in this module is trivial in positive dimensions, i.e. \( E^{ij}_2 = 0 \) when \( i;j > 0 \). Thus the spectral sequence collapses and we have

\[ H(S(\ );F_p) \to H(B;F_p) \to H(S(p);F_q) : \]

Also if \( q \neq p \) we have \( H(S(\ );F_q) \to H(S(p);F_q) : \)

Let \( X \) be a stable summand of \( BU(1)^p \) defined as follows. The action of \( F_p \) on \( BU(1)^p \) induces an action of \( F_p \) on the stable decomposition of \( BU(1)^p \) as a wedge of all smash products of length 1, \( \cdots;\cdots;p-1 \), say \( Y \), and a smash product of length \( p \). Then choose \( X \) such that \( NX = Y \), where \( N = 1+t+\cdots+t^{p-1}. \)

By the stable equivalence

\[ S(\ ;F_p) \overset{!}{\to} BU(1)^p \overset{!}{\to} Y \]

\[ (8) \]

we can consider $X$ as a stable summand of $S(\mathbb{P})$. For any choice of $X$, consider the composition of stable maps

$$f : S(\mathbb{P}) ! X^p \rightarrow T^\mathbb{P} E \rightarrow BU(1)^p \rightarrow BU(1)^p \rightarrow X :$$

(9)

We have to show that the stable map $\Delta_0 f$ induces an isomorphism in cohomology for any group of coefficients $\mathbb{F}_q$, $q$ a prime, and hence gives a stable equivalence by the stable Whitehead lemma. It follows from the above arguments that

$$H^*(S(\mathbb{P}); \mathbb{F}_q) = \Delta_0 H^*(B; \mathbb{F}_q) \rightarrow Tr_0 H^*(S(\mathbb{P}); \mathbb{F}_q);$$

and $H^*(S(\mathbb{P}); \mathbb{F}_q) = Tr_0 H^*(S(\mathbb{P}); \mathbb{F}_q)$; when $q \neq p$. The restriction of $Tr_0$ on $X$ induces a monomorphism on $Im Tr_0$ since by the transfer property (iv), $\Delta_0 Tr_0 = N$ and the restriction of $N$ on $H^*(X; \mathbb{F}_q)$ is a monomorphism. Hence $\Delta_0 f$ is an isomorphism and so is $\Delta_0 f$ by the commutative diagram

$$\begin{array}{ccc}
S(\mathbb{P}) & \longrightarrow & X^p \\
\Tr_0 & & \Tr \\
\mathbb{F}_q & & \mathbb{F}_q \\
S(\mathbb{P}) & \longrightarrow & E \rightarrow BU(1)^p
\end{array}$$

(10)

This proves Lemma 3.3.

\textbf{Proof of Theorem 3.2 (a)} We consider the restriction of any element $y 2 M U (X^p_h)$ to $M U (S(\mathbb{P}))$. By Lemma 3.3 we see this restriction has the form $\Delta_0 u + f w$ for some $u 2 M U (B)$, $w 2 M U (X)$. Since the composition $S(\mathbb{P}) ! X^p \rightarrow B$ coincides with $\Delta_0$, $\Delta(\mathbb{P})$ also restricts to $\Delta_0 (\mathbb{P})$. By diagram (10) there is an element $v 2 M U (B U(1)^p)$ such that $Tr(v)$ restricts to $f(w)$. By exactness

$$y = \Delta_0 u + Tr(v) + y_2 c_p;$$

for some $y_2 2 M U (X^p_h)$. For use in the proof of (c) we observe that (2), (8) imply $v$ can be chosen in the direct summand $M U [[x_1, \ldots, x_p]] = \langle x_1, \ldots, x_p \rangle$. Thus we can assume this expression for $y$ is unique and if $v \neq 0$ then $Tr(v)$ restricts nontrivia in $M U (S(\mathbb{P}))$.

Then suppose $cy = 0$. We know that $(\mathbb{C}) = \mathbb{C}$, hence $(c) = 0$ and $c Tr(v) = 0$ by Frobenius reciprocity. So we have $c'(\mathbb{P}) + cy_2 c_p = 0$. We want to prove $\Delta_0 (\mathbb{P}) 2 M U \rightarrow 0$. Applying $i$ we have $0 = i(c'(\mathbb{P})) + i cy_2 c_p = zu$ since $i = id$, $c = \Delta_0 (\mathbb{P})$, and $i(c_p) = 0$. Hence

u 2 Ann(z) = 1 mTr Zp. By naturality of the transfer ’ (u) 2 1 mTr . Thus c’ (u) = 0 and therefore cy1c2 = 0. Multiplication by c2 is injective by Lemma 3.3, hence cy1 = 0. Since dim(y1) = dim(y) - 2p iterating this argument gives us statement (a).

(b) This follows from the fact that the right homomorphism in the short exact sequence from Lemma 3.3 is multiplication by the Euler class cp(’).

(c) Let y 2 Ker . Since ’ = we have

0 = (Tr (v)) + (y1c2).

If the rst summand is not zero it restricts nontrivially in MU(S(| p)|) by definition of v. However the second summand restricts to zero since (c2) = x1 x2, (y1c2) = (y1)x1 x2 and x1 x2 restricts to zero as the Euler class. Hence both summands are zero. Furthermore multiplication by x1 x2 is a monomorphism hence (y1) = 0. So

y = ’ (u) + y1c2 = ’ (u) + (’ (u1) + y2c2)c2 = ’ (u) + ’ (u1)c2 + y2c2.

Repetition of this process proves (c).

(d) The fact that c1; c2 multiplicatively generate MU B(oU(1)) follows from Lemma 3.3. The relations c1 = c1, c2 = c2 follow from the bundle relation

@c = ( @c ( ) ) = ;

which in turn follows from transfer property (i).

So we have to prove that the Chern classes c; c1; c2 with these relations are a complete system of generators and relations. Let us use the splitting principle to write formally

u1 = c1 ( u );

u2 = c2 ( u );

Let F(x; y) = i j xiyj be the formal group law. Using the bundle relation above and applying the Whitney formula for the rst and second Chern classes, we obtain two relations of the form:

F (u1; c) + F (u2; c) = c1

and

F (u1; c)F (u2; c) = c2;

or in terms of c; c1 = u1 + u2; c2 = u1u2

F (u1; c) + F (u2; c) − c1 = c(2 + i j k c1 j c2 k ) = 0

and
\[ F(u_1; c)F(u_2; c) - c_2 = c(c_1 + \sum_{i,j,k} \gamma_{i,j,k} c_i c_j c_k) = 0; \] (13)
for some coefficients \( i,j,k \in \mathbb{M}U(\text{pt}). \)

We claim that relations (12) and (13) are equivalent to the following two obvious transfer relations for \( Tr : \mathbb{M}U[[x; tx]] \to \mathbb{M}U(B(oU(1))) \)
\[ cTr(1) = 0 \]
and
\[ cTr(x) = 0; \]

Rewrite relations (12) and (13) as follows:
\[ ca = 0; \text{ where } a = 2 + \sum_{i} \gamma_{1} c_i + \sum_{k} \gamma_{2} c_k; \]
\[ cb = 0; \text{ where } b = c_1 + 2 \sum_{i} \gamma_{2} c_i + \sum_{k} \gamma_{1} (c_k - c_1); \]
and the \( \gamma_{i,j,k} \) are the coefficients of the formal group law.

By the first part of Theorem 3.2, \( a \in \text{ImTr} \). Also by transfer property (vi)
\[ (a) = (Tr(1) + \sum_{k} X_{k} 11Tr(x^k)); \]

Thus by Lemma 2.1
\[ Tr(1) + \sum_{k} X_{k} 11Tr(x^k) = (F(u_1; c) + F(u_2; c) - c_1); \]

Similarly \( b \in \text{ImTr} \) and
\[ Tr(x) + \sum_{k} X_{k} 11Tr(c_2 x^k) = (F(u_1; c)c + F(u_2; c) - c_2); \]

Now since
\[ x^k = x^{k-1}(x + tx) - x^{k-2}(xtx); \]
transfer property (i) and the computation of \( Tr(x) \) is sufficient for the computation of \( Tr(x^k) \), \( k \geq 2 \) (see also Corollary 3.6, Remark 3.7). So we have
\[ Tr(1)(1 + g_0) + Tr(x)h_0 = (F(u_1; c) + F(u_2; c) - c_1); \] (14)
and
\[ Tr(1)g_1 + Tr(x)(1 + h_1) = (F(u_1; c)c + F(u_2; c) - c_2); \] (15)
where \( g_0; h_0; g_1; h_1 \in \mathbb{M}U(\text{pt}). \) This proves (d).

This completes the proof of Theorem 3.2.  \( \square \)
Formula (15) for computing Tr \( (x) \) is complicated; let us give a simpler form. Consider again (13). Note that the coefficient \( \gamma_{00k} \) M U \( (pt) \) contains a factor 2: the element

\[
c_1 + \gamma_{ijk} c^i c^j c^k
\]

annihilates \( c \) and hence belongs to \( \text{ImTr} \). On the other hand

\[
\text{Tr} = 1 + t; \quad (c) = 0; \quad (c_1) = x + tx; \quad (c_2) = xtx;
\]

hence applying we have that

\[
x + tx + \gamma_{0ijk}(x + tx)^j(xtx)^k
\]

belongs to \( \text{Im}(1 + t) \). So \( \gamma_{00k}(xtx)^k = 2\gamma_k(xtx)^k \), that is, \( \gamma_{00k} = 2\gamma_k \) for some coefficient \( \gamma_k \).

Recall that on the other hand \( F(c; c) = 0 \) that is \( 2c = o(c^2) \). So \( \gamma_{00k}c = o(c^2) \), hence taking into account the relation \( F(c; c) = 0 \) we can rewrite (13) after division by

\[
1 + \gamma_{1jk} c^i c^j c^k
\]

(the coefficient at \( cc_1 \)) as follows

\[
cc_1 = d_0c + d_2c_1^2 + d_3c_1 c_2 + \ldots
\]

where \( d_k = d_k(c; c_2) \) M U \( [(c; c_2)] \) and \( d_0(0; c_2) = 0 \); the lower index \( n \) indicates the coefficient at \( cc_1^n \). Since

\[
(\text{Tr} \ (x) - c_1) = 0;
\]

it follows from Theorem 3.2(c) that there exist elements

\[
\text{Tr} \ (x) = c_1 + \gamma_{ij} c^i c^j c^k
\]

such that

\[
\text{Tr} \ (x) = c_1 + \gamma_{ij} c^i c^j c^k;
\]

Using the inclusion \( i : B \to B(\ oU(1)) \) we have

\[
i (c_1) = i_0(c); \quad i \text{Tr} \ (x) = 0; \quad i \ (c_2) = 0;
\]

thus

\[
\gamma_{ij0} = -c;
\]

For the calculation of the other elements \( j \) recall that \( c\text{Tr} \ (x) = 0 \), hence

\[
cc_1^n = -c^n; \quad n \geq 1;
\]
where

\[ \frac{X}{j} = -c + \sum_{j=1}^{d_2} \]

Combining (16) and (17), we have the following:

**Proposition 3.4** The elements \( j, j > 0 \) can be determined from the recurrence relations which arise from the following formula in \( MU(B_1)[c_2] \)

\[ X = d_0 + \sum_{i} d_i i \]

**Proof** By definition the element \(-d_0 - \sum_{i=2}^{p} d_i i \) belongs to \( Ker \). On the other hand this element is annihilated by \( c \) hence

\[ -d_0 - \sum_{i} d_i i 2 \text{ mTr} \ \ K er( ) = 0 \]

by Lemma 2.1.

**Corollary 3.5** For the elements \( j \in MU(B_2) \), constructed in 3.4, the following formula holds in \( MU(B(Z=2)) \)

\[ \text{Tr} (x) = c_1 - c + \sum_{j=1}^{d_2} \]

In fact we have proved Theorem 3.1 for \( p = 2 \). The general case, analogous but more technical, is given next.

### 3.2 Proof of Theorem 3.1

Note that by the definition of \( k \) the difference \( \text{Tr} (k) - c_k \) is an element of \( K er( ) \). Thus Theorem 3.2 (c) implies existence of the elements \((k) \) in Theorem 3.1.

First let us elucidate the meaning of the relations

\[ \otimes c = \]

in the general case of \( B(\text{oU}(1)) \).

Again, we can use the splitting principle and write formally

\[ = 1 + 2 + \cdots + p; u_m = c_1( m); m = 1; \cdots; p; \]

Applying the Whitney formula for the relation
\[ 1 \odot c + p \odot c = 1 + p; \]
and taking into account that \( c_m = c_m(1) \) is the elementary symmetric function \( m(u_1; \ldots; u_p) \) we have
\[ m(F(u_1; c); \ldots; F(u_p; c)) = c_m; \]  
(18)
m = 1; \ldots; p, or in terms of \( c; c_1; \ldots; c_p \) we have
\[ c(p + \sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p) = 0; \]
and
\[ c((p - k)c_k + \sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p) = 0; \]  
(19)
for \( k = 1; \ldots; p - 1 \) and some \( \sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p \) \( \in \mathbb{F}_p \).

We claim that these relations are equivalent to the following obvious relations
\[ c\text{Tr} (1) = 0; \]
and
\[ c\text{Tr} (1_k) = 0; \]
for the elements \( 1_k \in \mathbb{F}_p \).

For the proof of our claim multiply the \( k \)-th relation from (19) by \( p_k = (p - k)^{-1} \) in \( \mathbb{F}_p \). Then by Theorem 3.2,Ann(c) coincides with \( \text{Tr} \) hence (18) implies that
\[ p_k(\sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p) = \text{Tr} (a_k); \]
for some \( a_k \) which we have to find. Let us write
\[ \sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p = \sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p; \]
\[ = k(1 + g_k^{(1; \ldots; p)}) + \sum_{j \neq k; 1; \ldots; p - 1} g_j^{(1; \ldots; p); \ldots; k; \ldots; p}; \]
\[ = N(1_k)(1 + g_k^{(1; \ldots; p)}) + \sum_{j \neq k; 1; \ldots; p - 1} N(1_j) g_j^{(1; \ldots; p); \ldots; k; \ldots; p); \]
Here the symbol \( k \) indicates absence of the corresponding term. So we have
\[ p_k(\sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p) = \text{Tr} (a_k); \]
and
\[ \sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p = \text{Tr} (a_k); \]
and
\[ [ \sum_{i_0; i_1; \ldots; i_p} c_{i_0} c_{i_1}^p \odot c_{i_p}^p - c] = \text{Tr} (a_k); \]

\[ = \text{Tr} (1)(1 + g_0(c_1; \ldots; c_p)) + \sum_{j=0}^{p-1} \text{Tr} (1_j g_0(c_j; c_{j+1}; \ldots; c_p)) \]

This proves our claim.

For computing \( (k)(c) \), we start with the equations (19) and rewrite them as

\[ cf_k(c; c_1; \ldots; c_p) = 0; \quad k = 1; \ldots; p - 1; \]  

(20)

These are equations in a power series algebra \( \mu B \)[[\( c_p \)]] since we know \( cc_k \in \mu B \)[[\( c_p \)]]

We now want to find explicitly formal series

\[ (k)(c) = \sum_{i=0}^{\infty} (k)(c)i c^i \]  

(21)

such that

\[ \text{Tr} (1_k) = c_k + (k)(c_p) \]

and hence

\[ cc_k = -c((k)(c_p))i; \quad j = 1; \]  

(22)

For this we want to replace the equations (20) by the equations

\[ cf_k(c; (1)(c_p); \ldots; (p-1)(c_p); c_p) = 0; \]  

(23)

where \( f_k \) is a series whose coefficient at \( (k) \) is invertible. In fact \( f_k = 0 \) since we know that \( \text{Ann}(c) = \text{Im} \text{Tr} \) and \( \text{Ker}( ) \setminus \text{Im} \text{Tr} = 0 \) by Lemma 2.1.

Then equating each coefficient of the resulting series

\[ g_k(c) = f_k(c; (1)(c_p); \ldots; (p-1)(c_p); c_p) = 0 \]  

(24)

in the ring \( \mu B \)[[\( c_p \)]] to zero we will obtain \( p - 1 \) infinite strings of equations in \( \mu B \)[[\( c_p \)]] Assuming \( (l) \) are already found for \( i < n \) we get

\[ (k) = n; k; ((l)i); n; \ldots; ((k)i)x; n; \ldots; ((p-1)i)x; n; \]  

(25)

a system of linear equations in \( (l), l = 1; \ldots; p - 1 \) with invertible determinant and coefficients in \( \mu B \)[[\( c_p \)]] Since the \( (l) \) are already known as \( l \)-th Chern classes of the bundle \( 1 + \ldots + p - 1 \), by induction on \( n \) we can solve formally (25) to get

\[ (k) = n; k; ((l)i)x; n; \]  

(26)

This gives \( (k) = (k)(z) 2 \mu B \) obviously satisfying our equations.
Now for the remaining equation (23) we proceed as follows: let us look at the term \( c f_k(0; 0; \ldots; 0; c_p) \) in equations (20). Note that \( f_k(0; 0; \ldots; 0; c_p) \) is divisible by \( p \):
\[
f_k(0; 0; \ldots; 0; c_p) = 1 \text{ mTr } f_k(0; 0; \ldots; 0; p) = 1 \text{ mN }
\]
\( f_k(0; 0; \ldots; 0; c_p) \) is divisible by \( p \).

Next using the relation \( [p] f(c) = 0 \) we know that \( pc \) is divisible by \( c^2 \); hence each occurrence of \( pc \) in these equations can be replaced by terms with higher powers of \( c \). So \( cf_k(0; 0; \ldots; 0; c_p) \) can be replaced by a term divisible by \( c^2 \).

Also the \( k \)-th relation from (20) contains the term \( c(p - k)c_k \), and for the condition (24) we have to multiply the \( k \)-th equation from (20) by \( (p - k)^{-1} \), the inverse of \( p - k \) in \( F_p \), and as above we can replace \( c(p - k)c_k \) by \( c_k + \text{ (terms divisible by } c^2) \). Then we use (22) and substitute the series \( (k) \) in the resulting equations, thus obtaining (23).

This completes the proof for \( E = MU \), which is the universal example of complex oriented cohomology theories. From this result we can descend to all \( E \). □

We now turn to computation of \( Tr \) in general.

**Corollary 3.6** For all primes \( p \), Theorem 3.1 enables us to explicitly compute the transfer homomorphism for those polynomials \( a \in MU[[x_1; \ldots; x_p]] \) for which \( Na = a + ta + \ldots + t^{p-1}a \) is symmetric in \( x_1; \ldots; x_p \).

**Proof** If \( Na = a_1(1; \ldots; p) + \ldots + a_{p-1}(1; \ldots; p) \), then
\[
Tr(a) = Tr(a) + \ldots + Tr(a)
\]
To see this let \( \bar{a} = a_1(1; \ldots; p) + \ldots + a_{p-1}(1; \ldots; p) \). Then \( N(a - \bar{a}) = 0 \), that is, \( a - \bar{a} 2 \text{ m}(1-t) \), hence \( Tr(a) = Tr(\bar{a}) \). □

**Remark 3.7** For \( p = 2 \) one has recurrence formulas for \( Tr(x^k) \), \( k \geq 1 \).
\[
Tr(x) = Tr(!)
\]
\[
Tr(x^k) = Tr(x^{k-1}c_1 - Tr(x^{k-2})c_2)
\]
This follows using the formula \( x^k = x^{k-1}(x + tx) - x^{k-2}(xtx) \).

4 Transferred Chern classes for $p$-coverings

If we consider a $p$-local complex oriented cohomology $E$ then by standard transfer arguments (see Lemma 4.3 below) $E(B_p)$ is isomorphic to the sub-ring of $E(B)$ invariant under the action of the normalizer of $p$ in $\mathbb{Z}$. The results of this section imply the elements $\sim^{(k)} 2 E(B)$ from Theorem 3.1 are invariant under this action. This defines elements $\sim^{(k)} 2 E(B_p)$ which we use for computing the transfer.

In this section we consider $BP(X_p^h)$ for $X = \mathbb{C}P^1$ and for the covering projection
$$p : E_p X_p^h ! X_p^h,$$
we give a formula for the transfer homomorphism
$$\text{Tr}_p : BP(X_p^h) ! BP(X_p^h)$$
using the elements $\sim^{(k)}$.

4.1 Brown-Peterson cohomology of $(\mathbb{C}P^1)_p^h$.

We need definitions analogous to those of Section 2, with the cyclic group replaced by the symmetric group. The $p$-fold product, $p$, of the canonical line bundle over $X_p^h$ extends to a $p$-dimensional bundle

$$p = E_p X_p^h$$

over $X_p^h$ classified by the inclusion $X_p^h = B(p o U(1)) ! B U(p)$. Let $c_i = c_i(p)$. Then $p(c_i) = c_i(p) = i$, the $i$-th symmetric polynomial in the $x_j$, where $BP(X_p^h) = BP[[x_1, \ldots, x_p]]$.

Then we have the projection
$$\pi : X_p^h ! B_p,$$
induced by the factorization $p o U(1) = U(1)^p = p$ and the inclusion
$$i : B_p ! X_p^h ;$$
induced by the inclusion of $p$ in $p o U(1)$.

Definition 4.1 Let $e_i = \text{Tr}_p(x_1x_2 \ldots x_i)$ for $i = 1, \ldots, p - 1$.

Lemma 4.2 $p(e_i) = i!(p - i)! i$. 

Malkhaz Bakuradze and Stewart Priddy

\[ p(\xi) = \text{Tr}_p(x_1x_2 \cdots x_i) = N_p(x_1x_2 \cdots x_i). \]

For each subset of \( i \) integers \( f_{j_1}; j_2; \cdots; j_l \) with \( 1 \leq j_k \leq p \), there are \( i! \) bijections \( f_{j_1}; j_2; \cdots; j_l \) and \( (p-i)! \) bijections \( f_{i+1}; i+2; \cdots; pg \). Thus there are \( i!(p-i)! \) summands of \( \prod_i x_{j_i} \) in \( N_p(x_1x_2 \cdots x_i) \).

We recall

\[ \text{BP}(B) = \text{BP } [[z]]/(p^2) \]

with \( jzj = 2 \). The corresponding computation for \( \text{BP}(B_p) \) is also known [19]. For the reader’s convenience we derive the result in a form useful for our purposes.

**Lemma 4.3** As a BP algebra

(i) \( \text{BP}(B_p) = \text{BP } [[y]]/(y \text{Tr}_p(1)) \);

where \( y \) and \( \text{Tr}_p(1) \) are uniquely determined by \( :_p(y) = z^{p-1} \) and

(ii) \( :_p(\text{Tr}_p(1)) = (p-1)! \text{Tr}(1) = (p-1)! [p](z) = z \).

In particular \( jyj = 2(p-1) \).

**Proof** (ii) Applying the double coset formula (transfer property (vi)) to

\[ \text{BP}(B_e) \xrightarrow{\text{Tr}_p} \text{BP}(B_p) \xrightarrow{i} \text{BP}(B) \];

the statement follows from Quillen’s formula (1).

(i) The relation \( y \text{Tr}_p(1) = 0 \) is a consequence of Frobenius reciprocity. To see that it is the defining relation we recall that the cohomology of \( B_p \) with simple coefficients in \( \mathbb{Z}(p) \) is

\[ H(B_p; \mathbb{Z}(p)) = \mathbb{Z}(p)[y]/(py) \]

where \( jyj = 2(p-1) \). This follows easily from the mod-\( p \) cohomology and the Bockstein spectral sequence.

Also \( H(B; \mathbb{Z}(p)) = \mathbb{Z}(p)[z]/(pz) \) where \( jzj = 2 \). The map \( :_p : B ! B_p \)

yields \( :_p(y) = x^{p-1} \).

Now the Atiyah-Hirzebruch-Serre spectral sequence for \( \text{BP}(B_p) \) is

\[ E_2 = H(B_p; \text{BP } ) = \text{BP } [y]/(py) = \text{BP}(B_p) \]

Since \( y \) is even dimensional, the sequence collapses at \( E_2 = E_1 \). Thus \( \text{BP}(B_p) \) is generated by \( y \) as a BP algebra.

For the group \( W = N_p = \mathbb{Z}/(p - 1), jWj \) is prime to \( p \), hence by the standard transfer argument \( \gamma_p : \text{BP}(B_p) \to \text{BP}(B) \) is an injective map of \( \text{BP} \) algebras. Since \( (yTr_p(1)) = pt^{p-1} \) plus terms of higher iteration, \( yTr_p(1) = 0 \) is the only relation.

Relating \( X_\mathfrak{h}^p \) and \( X_p \) we have a lift of

\[
\begin{array}{cc}
X_\mathfrak{h}^p & \sim_p X_p \\
\downarrow & \downarrow \\
B & B_p
\end{array}
\]

**Lemma 4.4** \( \sim_p (x_1) = k!(p-k)!Tr_p (x_k) \):

**Proof** Note that modulo \( \text{Im}(1-t) \) we have \( g(x_1x_2 \ldots x_k) = k!(p-k)! \) summed over \( k \). Applying the double coset formula

\( \gamma_p (e_k) = \gamma_p \text{Tr}_p (x_1x_2 \ldots x_k) = \gamma_p \text{Tr} g(x_1x_2 \ldots x_k) = k!(p-k)! \text{Tr}_p (x_k) \):

Let \( c = y 2 \text{BP}^{(p-1)}(X_\mathfrak{h}^p) \):

**Lemma 4.5** \( \text{Im}Tr_p \) is contained in the \( \text{BP} \) algebra generated by

\( c, e_1; \ldots; e_{p-1}; e_p \):

**Proof** By the K"unneth isomorphism,

\[
\text{BP}(X^p) = \text{BP}(X)^{\otimes p} = F \quad T
\]

as a \( \mathbb{F} \)-module, where \( F \) is free and \( T \) is trivial. Explicitly a \( \text{BP} \) basis for \( T \) is \( f x_1^i x_p^j \) 0g, while a \( \text{BP} \) basis for \( F \) is \( f x_1^i x_p^j \) 0g where not all the exponents are equal.

By Lemma 4.3 \( Tr_p(1) \) is a power series in \( c \). Now recall from [9], p. 44, that we can consider \( \text{BP}(X^p), X = \mathbb{C}P^1 \) as a free \( \text{BP} \) \( \mathbb{F}[[1; \ldots; p]] \) module generated by 1 and the elements \( x_1^i x_p^j \) \( F \), with \( 0 < i \leq j \leq p-1 \). So by Frobenius reciprocity it suffices to compute the transfer on these monomials.
Summed over the symmetric group $\prod_X X^p g(x_1^p x_p^p)$ is a symmetric function and hence has the form

$$g(x_1^p x_p^p) = 1s_1 + p-1s_{p-1} = X^{p} (!1s_1 + + ! p-1s_{p-1})$$

for the elements $!_k$ from Theorem 3.1 and symmetric functions $s_1;:::;s_{p-1}$. Hence modulo $\ker N = lm(1-t)$, we have the following equation in $F$

$$g(x_1^p x_p^p) = !1s_1 + + ! p-1s_{p-1}$$

The left sum consists of $(p-1)!$ elements each having the same transfer value. Also $!_k$ is the sum of $p_1^k_1$ elements $x_i_1 x_i_k$; on each of these elements the transfer evaluates to $\text{Tr}_p(x_1 x_k) = e_k$. Thus Frobenius reciprocity and Lemma 4.2 is all that is needed for computing $\text{Tr}_p$.

Recall the elements $(k)$ $2 B^p (B_p)$ derived from Theorem 3.1 by naturality. By the standard transfer argument again the map induced by $\sim_p : X^p_1$ $X^p_2$, the lift of $\sim_p : B_1^p B_2^p$, is also injective. Moreover for $B^p (X^p_1)$ the ring structure is completely determined by the following:

**Theorem 4.6** As a $B^p$ algebra

$$B^p (X^p_1) = B^p [[c_1;:::;c_{p-1};c_p]](\text{cTr}_p(1);c_r)$$

and one has the formula

$$e_k = k!(p-k)!c_k = i^0 (\sum (k)) c_j; \; k = 1;:::;p-1;$$

where the elements $(k)$ $2 B^p (B_p)$ are determined by

$$\sim_p (j^0) = k!(p-k)!j^0; \; j = 0;$$

For the proof we follow that of Theorem 3.2. Let

$$S(p) = E_p \text{S} = \text{E}_p$$

be the sphere bundle of the bundle of $(28)$. $X^p_1$ is homotopy equivalent to the disk bundle $D(p) = E_p D_1(p)$. Then we have the obvious inclusion $i_0 : B_1 p ! S(p) = E_p D_1(p)$. Thus stably $B_1 p$ is a wedge summand of $S(p)$. As for the other summand let

$$X_p = \prod_{i=1}^{p-1} E_i B U(1)^{\gamma_i}$$

By the standard transfer argument, localized at $p$, $X_p$ is a stable summand of $\prod_{i=1}^{p-1} E_i B U(1)^{\gamma_i}$ and hence of $E p \text{B U(1)}^p$. From this we derive the following result.
Lemma 4.7 One has a stable equivalence localized at $p$

\[ \text{'}_0 f_p : S(p)_p \simeq B_p X_p \]

with $f_p$, the composition of stable maps

\[ f_p : S(p) \to X_p \overset{Tr} \to E_p BU(1)^p \to X_p \]

Proof The inclusion $i_0$ splits off $\text{'}_0 H(B_p)$ in $H(S(p))$. Furthermore in mod-$p$ cohomology

\[ H(S(p)) = F_p[x_1, \ldots, x_p] \]

hence

\[ H(S(p)) = F_p[e_1, \ldots, e_{p-1}] \]

by Lemma 4.2.

Then $H := H^*(S(p))$ is a free module and $H(p; H) \overset{H}{=} H(p)$. Thus

\[ H(p; H) = H^p \text{ if } \leq 0 \]

\[ = 0 \text{ if } > 0 \]

Therefore there is an isomorphism

\[ H^*(S(p)) \to H(B_p) \]

where $S(p)_p \to S(p)$ is the projection. We have to prove that the first summand is $f_p H^*(X_p)$.

By naturality of the transfer we have the commutative diagram

\[ \begin{array}{ccc}
S(p) & \to & BU(1)^p \\
\downarrow & & \downarrow \\
Tr_0 & & Tr_p \\
S(p) & \to & X_p
\end{array} \]

Thus $f_p$ coincides with $f^\sim_p$, the map $Tr_0$ followed by the horizontal maps in the above diagram. We wish to show the restriction of $Tr_0$ to the image of $H(X_p)$ is an isomorphism onto $H(S(p))_p$.

Now considering the transfer for the $i$ coverings

\[ E_i BU(1)^{\wedge i} \to E_i BU(1)^{\wedge i} \]
it follows from transfer properties (ii) and (vi) that $H(E_i\rightarrow B\text{U}(1)^n)$ is a submodule of $H(E_i\rightarrow B\text{U}(1)^n)$ generated by $i$ norms of monomials in $x_1; x_2; \ldots; x_i$, with non-increasing degrees. From this it is straightforward that $H(X_p)$ and $H(S((\mathbb{P}^1)))_p$ have the same ranks in each dimension. Thus we are reduced to showing the desired map is injective.

However, for any monomial $x$ in $x_1; x_2; \ldots; x_i$, we have

$$\text{Tr}_0(N(x)) = i!\text{Tr}_0(x)$$

by naturality of the transfer. Thus the restriction of $\text{Tr}_0$ to the image of $H(X_p)$ will be a monomorphism if $\text{Tr}_0$ is non-zero on polynomials consisting of monomials with non-increasing degrees. This in turn will follow if the norm $N_p$ is non-zero on such polynomials. In fact we claim: 1) $N_p$ is non-zero on any monomial $x^l = x_1^{l_1}x_2^{l_p}$, all of whose exponents are not equal. Then we will show the coefficient of $x^l$ in $N_p(x^l)$ is prime to $p$. The isotropy subgroup of $x^l$ is the finite product $n_1 n_2 < p$ where $n_j$ is the number of terms of $j$ equaling $j$. This group has order $n_1!n_2!$ which is prime to $p$. Hence $N_p(x) = (n_1!n_2!)x^l$ + other monomials proving the claim.

Thus $\gamma_{0_\mathbb{P}}$ induces an isomorphism and hence is a $p$-local stable equivalence.

This implies the following:

**Lemma 4.8** The long exact sequence for the pair $(D(X_p); S(X_p))$ gives the following short exact sequence

$$0 \rightarrow \text{BP}(S(X_p)) \rightarrow \text{BP}(X_{h_p}) \rightarrow \text{BP}((X_{h_p})_p) \rightarrow 0.$$ 

Indeed the left arrow is an epimorphism by Lemma 4.7 and hence the right arrow is a monomorphism.

Now the proof of Theorem 4.6 is completely analogous to that of Theorem 3.2 taking into account additionally that any element $y \in 2\text{BP}(X_{h_p})$ has the form

$$y = \gamma(u) + g(e_1; \ldots; e_{p-1}) + y_1e_p$$

for some $u \in 2\text{BP}(X_{h_p})$, where $g$ denotes some formal power series and $y_1 \in 2\text{BP}(X_{h_p})$. This follows by Lemma 4.5 and Lemma 4.8.

5 Calculation of the elements $i_k$ and $i_{k-1}$ in Morava $K$-theory

In this section we work in Morava $K$-theory $K(s)$ and give an alternative, better algorithm for explicit computations.

Fix a prime $p$ and an integer $s \geq 0$, then $K(s) = \mathbb{F}_p[v_s; v_s^{-1}]$ with $j v_s = \sum_{j=0}^{p-2} (p^s - 1)$ and $v_s^p = v_s - 2(p^s - 1)$. By a result of Würgler [23] there is no restriction on $p$: although $K(s)$ is not a commutative ring spectrum for $p = 2$, we shall consider only those spaces whose Morava $K$-theory is even dimensional. This implies the deviation from commutativity is zero.

We recall
\[ K(s) (B_p) = K(s) [z](z^p) \]
where $jzj = 2$.

As in Lemma 4.3. we have:

**Lemma 5.1**

(i) $\pi : B_p ! B_p$ induces an isomorphism of $K(s)$ algebras
\[ \pi : K(s) (B_p) \rightarrow K(s) (B_p) \]
where $W = N/(z^p) = \mathbb{Z} = (p-1)$. Computing invariants yields
\[ K(s) (B_p) = K(s) [y](y^{m_s}) \]
where $m_s = [(p^s - 1)/(p-1)] + 1$.

(ii) $\text{Tr}_{p-1}(1) = -v_s y^{m_s-1}$.

Then combining Theorem 4.6 and Remark 2.2 we have

\[ K(s) (X^p_{h_p}) = K(s) [(c; \epsilon_1; \ldots; \epsilon_{p-1}; \epsilon_p)] = (c^{m_s}; \epsilon_1) \]

Our main result in this section is the following:

**Proposition 5.2** We can construct explicit elements $i_k$ such that

(1) In $K(s) (X^p_{h_p})$ the following formula holds
\[ c_k(\ ) = \text{Tr}_{p-1}(i_k) - \sum_{i=0}^{p-2} c_k(i)^{c_p}(\ ) \]

(2) In $K(s) (X_p)$ one has
\[ c_k \bigl( X_p^{i} \bigr) = \text{Tr}_p \left( x_1^{i} \cdots x_k \right) - \sum_{0 \leq i \leq p^2} \binom{-k}{i} \text{c}_p \left( x_1^{i} \cdots x_k \right); \]
with $\binom{-k}{i} = k!(p-k)! \binom{k}{i} k$.

(3) The value of $\text{Tr} \left( c_1 \left( i \right) \right)$ is determined by
\[ c_1 \left( i \right) = \text{Tr} \left( c_1 \left( i \right) \right) + \sum_{1 \leq j \leq s-1} X \binom{p^2-p}{j} \binom{p^{2^{(s-1)}}-1}{p^{2^{(s-1)}}-1} \]
where $i$ is the pullback of the canonical line bundle by projection $BU(1)^p$ on the $i$-th factor.

We are grateful to D. Ravenel for supplying us with the proof of the following result.

**Lemma 5.3** For the formal group law in Morava $K$-theory $K(s)$, $s > 1$, we have
\[ F \left( x; y \right) = x + y - \sum_{0 \leq j < p} X \binom{p^2}{j} \left( x^{p^2-j} y^{p^2-j} \right) \]
modulo $x^{p^{2(s-1)}}$ (or modulo $y^{p^{2(s-1)}}$).

**Proof** This result can be derived from the recursive formula for the FGL given in 4.3.9 [17]. For the FGL in Morava $K$-theory it reads
\[ F \left( x; y \right) = \sum_{0 \leq j < p} X \binom{p^2}{j} \left( w_i \right) x^{p^2-j} \]
where $w_i$ is a certain homogeneous polynomial of degree $p^2$ defined by 4.3.5 [17] and $e_i = (p^2 - 1) = (p^2 - 1)$. In particular $w_0 = x + y$,
\[ w_1 = - \sum_{0 \leq j < p} X \binom{p^n}{j} x^{p^n-j}; \]
and $w_i \geq (x^p, y^p)$.

We find it more convenient to express $F \left( x; y \right)$ as
\[ F \left( x; y \right) = F \left( x + y; v_s w_1 \right) x^p \cdots x^{p^{(s-1)}}; v_s w_2 \left( x; y \right) x^{p^{2(s-1)}}; \cdots; \]
Then for \( s > 1 \) we can reduce modulo the ideal \( v^2 s (x^{p^2(s-1)}, y^{p^2(s-1)}) \) and get
\[
F(x; y) = F(x + y, v_s w_1(x; y)^{p^2-1}) = w_2(x + y, v_s w_1(x; y)^{p^2-1})^{p^2-1},
\]
and modulo \( v_s + p^2 - 1 \), we have
\[
F(x; y) = x + y + v_s w_1(x; y)^{p^2-1}.
\]

Let us write for short
\[
k = k(x; F(x; z), \ldots, F(x; (p - 1)z)).
\]

**Corollary 5.4** The following formula holds in \( K(s) (BU(1) B) \)
\[
k = -X^{(k)}_i \frac{i}{p^2} x^k v_s z^{p^2-1},
\]
where \( X^{(k)}_i \) are polynomials in \( z^{p^2-1} \) and \( \frac{(i)}{0} = 0, j = 1; \ldots; p - 2, \frac{(p-1)}{0} = -z^{p^2-1}. \)

Proof. For \( 1 \leq k \leq p - 1 \), equating the coefficients of \( x^{(p)}, 1 \leq i \leq p^2 \), gives a system of linear equations with invertible matrix of the form \( I + \text{nilpotent} \). Thus the elements \( X^{(k)}_i ; ; X^{(k)}_p \) can be defined as the solution of this system.

Of course, equating the coefficients at \( x^i \) for \( i \neq p, 2p; \ldots; p^2 + 1 \) will produce other equations in \( X^{(k)}_i ; ; X^{(k)}_p \). But these equations are derived from the old equations above. These additional equations make the matrix upper triangular.

Now, let us prove Proposition 5.2 and show that one necessarily has \( X^{(k)}_i = X^{(k)}_i \), \( i = 0; \ldots; p^2 \) for \( X^{(k)}_i \) encountered in Corollary 5.4. Thus by Lemma 5.1, \( X^{(k)}_i \) is invariant under the action of \( W \) and we can define \( X^{(k)}_i \) by \( -; X^{(k)}_i \) as \( k!(p - k)! X^{(k)}_i \).

The diagonal map \( BU(1) ! BU(1)^p \) induces an inclusion \( BU(1) ! X^p \) and the commutative diagram
\[
\begin{array}{ccc}
E & \xrightarrow{1} & E \\
\downarrow & & \downarrow \\
B & \xrightarrow{?} & X^p
\end{array}
\]
Then \((1 \rightarrow 1) \rightarrow 1 \rightarrow 1\) hence by transfer properties (i) and (iv) we have for the transfer \(\operatorname{Tr} = \operatorname{Tr}(1 \rightarrow 1)\):

\[
\operatorname{Tr} ((1 \rightarrow 1) \rightarrow 1) = p^{-1} x^k \operatorname{Tr} (1) = p^{-1} x^k v_s z^{p^s-1}.
\]

On the other hand by the existence of the elements \([k]_i\) (Theorem 3.1) we have

\[
\operatorname{Tr} ((1 \rightarrow 1) \rightarrow 1) = k(x; F(x;z); \ldots; F(x;(p-1)z)) + \sum_{i=0}^{p-1} \left( \sum_{j=1}^{p^s-1} \left( v_s^{(k)} - i \right) x^k v_s z^{p^s-1} \right):
\]

restricts to \(p \otimes i \rightarrow 0 \rightarrow B U(1) \rightarrow B\), thus \(c_k(1) \rightarrow k(x; F(x;z); \ldots; F(x;(p-1)z))\); by Lemma 5.3 and the fact that \(z^{p^s} = 0\), \(i\mid z\) may be replaced by \(iz\). By Corollary 5.4

\[
k(x; F(x;z); \ldots; F(x;(p-1)z)) = \sum_{i=0}^{p^s} \left( \sum_{j=1}^{p^s-1} \left( v_s^{(k)} - i \right) x^k v_s z^{p^s-1} \right):
\]

Then the restriction of \((1 \rightarrow 1) \rightarrow 1\) to \(K\) is a monomorphism [11]. This proves Proposition 5.2.1 and shows \([k]_i = [k]_i\) for \(0 \leq i \leq p^s\) and zero otherwise. Statement 2) follows from Lemma 4.4. Then 3) follows from the following explicit formula for 1:

**Lemma 5.5** In \(K(s) (B \rightarrow B U(1))\) one has

\[
1 = v_s z^{p^s-1} x + \sum_{i=1}^{p-1} x^{p^s-1} \left( p^{(k)} \right) ;
\]

**Proof** One has

\[
1 = x + F(x;z) + F(x;(p-1)z) = x + x + z + v_s w_1(x^{p^s-1}; z^{p^s-1}) + F(x;(p-1)z) + v_s w_1(x^{p^s-1}; ((p-1)z)^{p^s-1})
\]

\[
= p x + \frac{p(p-1)z}{2} + v_s w_1(x; iz)
\]

\[
= v_s @ \left( p^{(k)} \right) ;
\]

\[
= v_s @ (p^{(k)} - p^{(k)} ; x^{p^s-1} z^{p^s-1})
\]

\[
= v_s @ (p^{(k)} ; x^{p^s-1} z^{p^s-1})
\]

Thus

\[
1 = -v_s (p-1)p^{-1} z^{p-1} x^{p-(p-1)} = v_s z^{p^2-p^2-1} x^{p^2-1}; \quad (32)
\]

Now since \( F(x; z)^p = x^p + z^p \), one has \( \overline{p} = (x(x + z))(x + (p-1)z)^p \).

But again we have \( x(x + z) = x^p - xz^{p-1} \). Substituting this one obtains

\[
v_s(z^{p^2-1}x + \sum_{i=1}^{X^{-1}} z^{p^2-p^i} p_{p}^{i-1}) = v_s z^{p^2-1} x + z^{p^2-p} (x^p - z^{p-1}x)^{-1}.
\]

But it is straightforward to see that

\[
\sum_{i=2}^{X^{-1}} z^{p^2-p^i} (x^p - z^{p-1}x)^{-1} = z^{p^2-p^2-1} x^{p^2-1} - z^{p^2-p^2} x^p.
\]

Hence one has

\[
v_s(z^{p^2-1}x + \sum_{i=1}^{X^{-1}} z^{p^2-p^i} p_{p}^{i-1}) = v_s z^{p^2-1} x + z^{p^2-p} p_{p}^{i-1} x^{p^2-1} - z^{p^2-p^2} x^p; \quad (33)
\]

Now one has

\[
z^{p^2-p} F(x; k z) = z^{p^2-p}(x + k z + v_s w_1(x^{p^2-1}; (k z)^{p-1})) = z^{p^2-p}(x + k z);
\]

hence \( z^{p^2-p} p_{p} = z^{p^2-p} x(x + z) = z^{p^2-p} x^{p^2-1} \) (x + (p-1)z) = z^{p^2-p} x^p - z^{p-1}x).

Substituting this into (33) gives

\[
v_s z^{p^2-1} x + \sum_{i=1}^{X^{-1}} z^{p^2-p^i} p_{p}^{i-1} = v_s z^{p^2-p^2-1} x^{p^2-1},
\]

which is 1 by (32).
We now compute some of the elements \( (k) \) and \( \sim (k) \).

First recall from [8], [17] that generators for

\[
\mathbb{BP}_* \mathbb{H} \mathbb{BP}_* \mathbb{Z}(p)[v_1; v_2; \cdots] \quad \mathbb{Z}(p)[m_1; m_2; \cdots]
\]

\[ jv_n = 2(p^n - 1) = jm_n \]

are given by

\[
v_n = pm_n - \sum_{i=1}^{m} v_i^{n-i}
\]

Given a formal group law over a graded ring \( R \);

\[
F(x; y) = \sum_{i,j} R_{ij} x^i y^j 2R [x; y]; \quad R_{ij} 2R 2(i+j-1)
\]

there is a ring map \( g: MU \rightarrow R \) which induces the formal group law; that is \( g (MU_{ij}) = R_{ij} \).

We use also the following well known formulas

\[
F(x; y) = \exp(\log x + \log y) \quad \text{and} \quad \log x = \sum_{n=0}^{X} m_n x^{n+1}
\]

for computing the elements \( i \) in \( BP \) theory by the algorithm of Section 3.

**Example 1** For \( 12 \mathbb{BP}(\mathbb{BZ}=2) = \mathbb{BP} [z] = [2(z)] \) we have modulo \( z^8 \):

\[
1 = v_1^2z^2 + (v_1^2 + v_2)z^3 + v_1z^4 + (v_1^3 + v_1v_2)z^5 + (v_1^4v_2 + v_2^2 + v_3)z^6.
\]

Next we give some results of calculations in Morava \( K \)-theories, where the formulas are more tractable. In the following examples \( (k) \) coincides with the coefficient at \( \frac{1}{p} \) in the expression for \( k \) from Corollary 5.4, \( y = z^{p-1} \), and \( \sim (k) = k!(p-k)! \) \( (k) \).

**Example 2** \( p = 3; s = 2 \)

\[
1 = v_2y^3 z + v_2y^4x.
\]

\[
2 = 2v_2^2y^3 z^4 + 2v_2y^2 z^2 + v_2x^2y^4 + 2y.
\]

**Example 3** \( p = 5; s = 3 \)
1 = v_3 y^{25} s^5 + v_3 y^{30} s + v_3 y^{31} x.

2 = 4v_3^2 y^{25} s^{30} + 4v_3^2 y^{30} s^{26} + 3v_3 y^{19} s^{10} + v_3 y^{24} s^{6} + 3v_3 y^{29} s^{2} + 2v_3 y^{31} x^2.

3 = 2v_3^3 y^{25} s^{55} + 2v_3^3 y^{30} s^{51} + v_3^2 y^{19} s^{35} + 2v_3^2 y^{24} s^{31} + v_3^2 y^{29} s^{27} + 2v_3 y^{13} s^{15} + v_3 y^{18} s^{11} + v_3 y^{23} s^{7} + 2v_3 y^{28} s^{3} + 2v_3 x^3 y^{31}.

4 = 4v_3^4 y^{25} s^{80} + 4v_3^4 y^{30} s^{76} + 4v_3^3 y^{19} s^{60} + 3v_3^3 y^{24} s^{56} + 4v_3^3 y^{29} s^{52} + 4v_3^2 y^{13} s^{40} + 2v_3^2 y^{18} s^{36} + 2v_3^2 y^{23} s^{32} + 4v_3^2 y^{28} s^{28} + 4v_3 y^{7} s^{20} + v_3 y^{12} s^{16} + 4v_3 y^{17} s^{12} + v_3 y^{22} s^{8} + 4v_3 y^{27} s^{4} + v_3 x^4 y^{31} + 4y.

6 Transfer and \( K(s) \) \( (X^\mathcal{P})_p \)

Let \( X \) be a CW complex whose Morava \( K \)-theory \( K(s)(X) \) is even dimensional and finitely generated as a module over \( K(s) \).

In this section we study the transfer homomorphism in this more general context. We extend some results of Hopkins-Kuhn-Ravenel [10] to spaces. We consider the Atiyah-Hirzebruch-Serre (later abbreviated AHS) spectral sequence:

\[
E_2 : (\ ; X) = H (\ ; K(s)(X^\mathcal{P})) \ K(s)(X^\mathcal{P});
\]

By the K"unneth isomorphism

\[
K(s)(X^\mathcal{P}) \to (K(s)(X)^{\otimes p});
\]

Then \( K(s)(X^\mathcal{P}) \) is a module where acts by permuting factors (see [10], Theorem 7.3).

An element \( x \in K(s)(X) \) is called good if there is a finite cover \( Y \). \( X \) together with an Euler class \( y \in 2 K(s)(Y) \) such that \( x = Tr(y) \) where \( Tr : K(s)(Y) \) is the transfer. The space \( X \) is called good if \( K(s)(X) \) is spanned over \( K(s) \) by good elements.

Let \( y = 1(z) \), where

\[
' : X^\mathcal{P}_h \to \mathcal{B}
\]

is the projection and let \( f_{x,y} : 2 J \) be a \( K(s) \) basis for \( K(s)(X) \). Hunton [12] has shown that if \( K(s)(X) \) is concentrated in even dimensions then so is \( K(s)(X^\mathcal{P}) \). We adopt the stronger hypothesis that \( X \) is good and derive a stronger result, following the argument of [10] Theorem 7.3 for classifying spaces.
Proposition 6.1 Let $X$ be a good space.

(i) As a $K(s)$ module $K(s) (X_p)$ is free with basis

$$f \gamma^i \otimes (x_j)^{op} \ j \ 0 \ i < p; j \ 2 \ J \ g$$

and

$$f \ X \ 1 \otimes x_{i_1} \otimes x_{i_2} \otimes \ldots \otimes x_{i_p} \ j \ 1 \ 2 \ P \ g$$

where $l = f(i_1; i_2; \ldots; i_p)$ runs over the set $P_p$ of $p$-equivalence classes of $p$-tuples of indices $i_j \ 2 \ J$ at least two of which are not equal.

(ii) $X_p$ is good.

Proof (i) By the Künneth isomorphism,

$$K(s) (X) \otimes P = F \ T$$

as a $-module, where $F$ is free and $T$ is trivial. Explicitly a $K(s)$ basis for $T$ is $f(x_i) \otimes i \ 2 \ J \ g$, while a $K(s)$ basis for $F$ is $f x_{i_1} \otimes x_{i_2} \otimes \ldots \otimes x_{i_p} ; i \ 2 \ J \ g$

where not all the factors are equal. Then

$$H ( \ ; F ) = F \ if \ = 0$$

$$= 0 \ if \ > 0$$

and

$$H ( \ ; T ) = H ( B ) \otimes T :$$

Thus $E_2^0 ( \ ; X ) = K(s) (X_p) = F \ T$.

To continue the proof we recall the covering projection

$$E \ X_p \ X_h$$

its associated transfer homorphism

$$\text{Tr} = \text{Tr} : K(s) (X_p) \ K(s) (X_h);$$

and induced homomorphism

$$: K(s) (X_p) \ K(s) (X) :$$

Similar maps are defined for the group $p$. Then $\text{Tr} = N$, where $N = N$ is the trace map.

Thus we have established the following lemma.
Lemma 6.2 If \( y \in K(s) (X^p) \) is good then there exists a good element \( z \in K(s) (X^p_h) \) such that \( (z) = N(y) \).

Lemma 6.3 If \( x \in K(s) (X) \) is good then there is a good element \( z \in K(s) (X^p_h) \) such that \( (z) = x^p \).

Proof By assumption there is a finite covering \( f : Y \to X \) and an Euler class \( e \in K(Y) \) such that \( x = Tr(e) \). Now consider the covering \( f : Y^p \to X^p \) which extends to a covering \( 1 : Y^p_h \to X^p_h \) and yields a map of coverings

\[
\begin{array}{c|c|c}
E & Y^p & Y^p_h \\
\hline
1 & 1 \\
\hline
E & X^p & X^p_h
\end{array}
\]

The class \( e^p \) is an Euler class for \( Y^p \). Since the transfer is natural and commutes with tensor products we have

\[
Tr (1 \otimes e^p) = Tr (e^p) = Tr (e) \otimes \otimes Tr (e) = x^p; \]

Corollary 6.4 \( E_2^{0,0} ( ; X) \) consists of permanent cycles which are good.

Thus as differential graded \( K(s) \) modules, there is an isomorphism of spectral sequences

\[
(E_r : ( ; pt)) \otimes_{K(s)} T \to E_r : ( ; X);
\]

Thus it follows that as a \( K(s) \) algebra, \( K(s) (X^p_h) \) is generated by \( K(s) (B^H), T, \) and \( F \).

(ii) The proof of [10] Theorem 7.3 carries over. This completes the proof of Proposition 6.1.
Remarks (1) From the periodicity of the cohomology of a cyclic group [5] Proposition XII, 11.1, we have isomorphisms
\[ H^t( ; K(s)(X_p)) \cong H^{t+2}( ; K(s)(X_p)) \]
for \( t > 0 \) and
\[ H^0( ; K(s)(X_p)) = \text{Im}(N) \cong H^2( ; K(s)(X_p)) : \]
Thus multiplication by \( z \) is also injective on \( T \) at the \( E_2 \) term.

(2) \( \text{Tr} = N, \text{ thus modulo } \ker(N) \) we have
\[ \text{Tr} (x_{i_1} \otimes x_{i_2} \otimes \cdots \otimes x_{i_p}) = 1 \otimes x_{(i_1)} \otimes x_{(i_2)} \otimes \cdots \otimes x_{(i_p)} : \]
Note that if the \( i_j \) in (38) are equal, the right hand side is zero. However
\[ \text{Tr} (x_j^{\otimes p}) = 1 \otimes x_j^{\otimes p} \text{ Tr (1):} \]
We now turn to \( K(s)(X_h^p) \).
Let \( c = \gamma (y) \) where \( : E_p X^p \to B_g \) is the projection.

Proposition 6.5 Let \( X \) be a good space. As a \( K(s) \) module \( K(s)(X_h^p) \) is free with basis
\[ f c \otimes (x_j)^{\otimes p} j 0 \quad i < m_j j 2 J \quad g \]
and
\[ f x_{(i_1; i_2; \cdots ; i_p)} = 1 \otimes x_{i_1} \otimes x_{i_2} \otimes \cdots \otimes x_{i_p} j 1 2 E_p \quad g \]
where \( l = f(i_1; i_2; \cdots ; i_p) g \) runs over the set \( E_p \) of \( p \)-equivalence classes of \( p \)-tuples of indices \( i_j 2 J \) at least two of which are not equal.

Proof Since \( jW_j \) is prime to \( p \), the result follows from the AHS spectral sequence, as in the proof of Proposition 6.1. \( \Box \)

7 Applications

7.1 \( o(Z=p^n) \)
We now turn to \( G_n = o(Z=p^n) \) where \( = Z=p \). Then \( B G_n = X_h^p \) for \( X = B Z=p^n \). Consider the AHS spectral sequence for
\[ B(Z=p^n)^p ! B G_n ! B : \]
Then
\[ E_2^{p,q} = H(\pi K(B(\mathbb{Z}/p^n))) \]
where
\[ K(\pi) B(\mathbb{Z}/p^n) = (K(\pi) B(\mathbb{Z}/p^n))^{\mathbb{F}} T; \]
where \( F \) and \( T \) as in (36) above are free (resp. trivial) modules.

Let \( \gamma = \gamma(z) \) where \( K(\pi) B(\pi) = K(\pi) B(\pi) \) as above.

**Proposition 7.1** As a \( K(\pi) \) module \( K(\pi) B G_n \) is free with basis
\[ f \gamma(\pi) (z^i)^{\pi} \quad i < p^n; 0 \quad j < p^n g \]
and
\[ f = \gamma 1 \otimes z^{i_1} \otimes z^{i_2} \otimes \cdots \otimes z^{i_p} \quad j < p^n g; \]
where \( l = f(i_1; i_2; \cdots; i_p) g \) runs over the set \( P_n(n) \) of \( \pi \)-equivalence classes of \( \pi \)-tuples of integers \( f_0 < p^n g \) at least two of which are not equal.

**Proof** This spectral sequence computation is exactly analogous to that of Proposition 6.1.

**Remarks** (i) For \( X = \mathbb{C}P^1 \), Proposition 7.1 gives another derivation of \( K(\pi) X_n \). Since \( \mathbb{C}P^1 = \lim \mathbb{B} (\mathbb{Z}/p^n) \pi \), we have \( K(\pi) X_n = \lim K(\pi) (BG_n) \).

(ii) \( G_n \) is good for \( K(\pi) \) by [10] Theorem 7.3.

By analogy with Section 6 we have the following:

**Lemma 7.2** (i) \( \text{Im(Tr) } \gamma = 0 \)
(ii) \( \text{Tr(1) } = \psi \gamma^{p^n-1} \)
(iii) \( \text{If } y 2 T \text{ then } \text{Tr(1) } = y \text{ Tr(1) } \)

Finally we consider the case \( p = 2 \) where \( c = \gamma \). If \( n = 1, G_n \) \( D_8 \), the dihedral group of order 8; the rings \( K(\pi) B D_{2n} \) were determined by Schuster [20],[21]. In general we have a partial result:

**Proposition 7.3** Let \( p = 2 \). As a \( K(\pi) B(\pi) \) algebra, \( K(\pi) B G_n \) is generated by \( e_1; c_2 \) subject to the relation \( e_1 c = 0 \) and the relations \( c_1^{2n} = c_2^{2n} = 0 \) modulo terms divisible by \( c \).
Proof. \( e_1 c = 0 \) by Lemma 7.2. The other relations hold in the \( E_1 \) term of the spectral sequence. The only possible extensions are those on the bar, involving \( e_1 ; c_2 \).

\[ \square \]

Similar results hold for \( p \circ \mathbb{Z} = p \) and \( p \circ p \) for \( p \) odd.

7.2 \( p \)-groups with cyclic subgroup of index \( p \).

In this section we consider the class of \( p \)-groups with a (necessarily normal) cyclic subgroup of index \( p \). It is known [3], Theorem 4.1, Chapter IV, that every \( p \)-group of this form is isomorphic to one of the groups:

(a) \( \mathbb{Z} = q \) \( (q = p^n; n \geq 1) \).

(b) \( \mathbb{Z} = q \times \mathbb{Z} = p \) \( (q = p^n; n \geq 2) \), where the canonical generator of \( \mathbb{Z} = p \) acts on \( \mathbb{Z} = q \) as multiplication by \( 1 + p^{n-1} \). This group is called the modular group if \( p \neq 3 \) and the quasi-dihedral group if \( p = 2; n = 4 \).

For \( p = 2 \) there are three additional families.

(d) Dihedral 2-groups \( D_{2m} = \mathbb{Z} = m \times \mathbb{Z} = 2 \) \( (m \geq 2) \), where the generator of \( \mathbb{Z} = 2 \) acts on \( \mathbb{Z} = m \) as multiplication by \( -1 \). If \( m = 2^n \), \( D_{2m} \) is a 2-group. Note that \( D_4 \) belongs to (b) and \( D_8 \) belongs to (c).

(e) Generalized quaternion 2-groups. Let \( H \) be the algebra of quaternions \( \mathbb{R} i j k \). For \( m \geq 2 \) the generalized quaternion group \( Q_{4m} \) is defined as the subgroup of the multiplicative group \( H \) generated by \( x = e^{i m \pi} \) and \( y = i \). \( \mathbb{Z} = 2m \) generated by \( x \) is normal and has index 2. If \( m \) is a power of 2, \( Q_{4m} \) is a 2-group. In the extension \( 0 \to \mathbb{Z} = 2m \to Q_{4m} \to \mathbb{Z} = 2 \to 0 \) the generator of \( \mathbb{Z} = 2 \) acts on \( \mathbb{Z} = 2m \) as \(-1\). In particular \( Q_8 \) is the group of quaternions \( 1; i; j; k \).

(f) Semi-dihedral groups. \( \mathbb{Z} = q \times \mathbb{Z} = 2 \) \( (q = p^n; n \geq 3) \), where the generator of \( \mathbb{Z} = 2 \) acts on \( \mathbb{Z} = q \) as multiplication by \( -1 + 2^{n-1} \).

Consider now the task of computing the stable Euler class, \( \text{Tr}_G(1) \), for the universal \( G \)-covering \( \tilde{E}G \to BG \).

For the case (a) there is the well known formula of Quillen (1)

\[ \text{Tr}_{\mathbb{Z} = q}(1) = [q]_F(z) = z \]

in \( \text{MU}(BG) = \text{MU}([[z]]) = [[q]](z) \).

For the case (b) the answer follows from transfer property (ii): \( \text{Tr}_G = \text{Tr}_{Z^{eq}} \wedge \text{Tr}_{Z=p} \).

In cases (d), (e) and (f) \( \text{Tr}_G \) is the composition of two transfers \( \text{Tr}_{Z^{eq}} \) and \( \text{Tr}_{C;G} : MU(BC) \to MU(BG) \), where \( C \) is the corresponding cyclic subgroup. So we have to compute \( \text{Tr}_{C,G}(z^i), i \geq 1 \) and we can apply our results for \( BZ=2O(1) \), namely Remark 3.7.

Similarly for the case (c), \( \text{Tr}_G \) is the composition \( \text{Tr}_{Z^{eq}} \wedge \text{Tr}_{Z=p} \) and we can apply Corollary 3.6.

This task is trivial for wreath products \( Z=prZ=p^n \) since \( \text{Tr}_{Z=p^n}(1) \) is symmetric in \( z_1; \ldots; z_p \) in the ring
\[
MU((BZ=p^n)^p) = MU([z_1; \ldots; z_p])=([p^n](z_1); \ldots; [p^n](z_p))
\]
and hence invariant under the \( Z=p \) action. So in this case we need only Quillen’s formula.

Finally we note that if \( G \) is the modular group of case (c), Brunetti [4] has completely computed the ring \( K(s)BG \). The relations are quite simple but the generators are technically complicated. In a future paper we plan to use transferred Chern classes to give a more natural presentation.

### 7.3 Other examples

Consider the semi-direct products \( G = (Z=p)^n \rtimes Z=p \) where the generator of \( Z=p \) acts on \( H_n = Z=p[T]=T^n \) by \( 1 - T = T, 1 \leq n \leq p \). Then every \( Z=p[T]=Z=p \)-module is a direct sum of the modules \( H_n \). As shown by Yagita [24] and Kriz [14], these semi-direct products are good in the sense of Hopkins-Kuhn-Ravenel.

We recall
\[
K(s)(B(Z=p)^n) = K(s)[[z_1; \ldots; z_n]](z_i^{p^n});
\]
where \( z_i \) is the Euler class of a faithful complex line bundle \( T_i \) on the \( i \)-th factor. Then \( Z=p \) acts on \( K(s)[z_1; \ldots; z_n](z_i^{p^n}) \) by
\[
: z_i \rightarrow F_{K(s)}(z_i; z_{i+1}); \quad z_{n+1} := 0;
\]
where \( F_{K(s)} \) denotes the formal group law for Morava \( K \)-theory.

Our aim is to show how to compute the stable Euler classes in terms of characteristic classes and the formal group law.

The transfer \( \text{Tr} : K(s)EG \rightarrow K(s)BG \) is the composition of two transfers
\[
\text{Tr}_1 : K(s)E((Z=p)^n) \rightarrow K(s)B((Z=p)^n)
\]
and

$$\text{Tr}_2 : K(s) \ B((\mathbb{Z} = p^n)) ! K(s) \ \text{B } G.$$ 

Recall also that

$$\text{Tr}_1(1) = z_1^{p^s-1} \ z_n^{p^s-1}.$$ 

It is easy to see that in $K(s) ((B \mathbb{Z} = p^n)$ we have

$$e^{p^s-1}(i_1(1)) \ e^{p^s-1}(i_n(1)) = z_1^{p^s-1} \ z_n^{p^s-1},$$

where $e$ is the Euler class and $1 \ i_1 \ < \ i_n \ < \ p$. Then recall the elements $!_n$ from Theorem 3.1 and let $!_n(l)$ be the sum of the same monomials after raising to the power $l$. Since $!_n(l)$ consist of $p^{-1} p_n$ summands and $p^{-1} p_n = (-1)^{n-1} \text{ mod } p$, we have that in $K(s) ((B \mathbb{Z} = p^n)$

$$(!_n(p^s - 1)) = (-1)^{n} z_1^{p^s-1} \ z_n^{p^s-1} = n;$$

where the map , defined in Section 2, sends $i = t^{-1}_{i-1}$ to $i^{-1}_{i-1}$. Hence

$$\text{Tr}_G(1) = \text{Tr}_2(\text{Tr}_1(1)) = \text{Tr}_2((-1)^n \ n \ (\!_n(p^s - 1))) = (-1)^n n \text{Tr}_2((\!_n(p^s - 1)));$$

and we have to apply Corollary 3.6.
