Abstract

Let $\text{GL}_1(R)$ be the units of a commutative ring spectrum $R$. In this paper we identify the composition

$$R : \text{BGL}_1(R) \to K(R) \to \text{THH}(R) \to \Omega^1(R);$$

where $K(R)$ is the algebraic K-theory and $\text{THH}(R)$ the topological Hochschild homology of $R$. As a corollary we show that classes in $i_{-1}R$ not annihilated by the stable Hopf map $2\pi_1(S^0)$ give rise to non-trivial classes in $K_i(R)$ for $i \geq 3$.

1 Introduction

Given a connective (symmetric) ring spectrum $R$, we follow Waldhausen and define the units $GL_1(R)$ to be the union of the components in $\Omega^1(R)$ that correspond to units in the discrete ring $\mathcal{O}R$. With this definition $GL_1(R)$ is a group-like monoid whose group of components equals $GL_1(\mathcal{O}R)$. As in the case of a discrete ring there is a natural map $BGL_1(R) \to K(R)$ to the algebraic K-theory of $R$. If $R$ is a commutative discrete ring this is split by the determinant, but the definition of the determinant does not generalize to the setting of ring spectra and the above map is in general not split, even if $R$ is commutative. For example, Waldhausen shows [21] that this fails quite badly for the sphere spectrum. However, it turns out that the notion of traces of matrices does generalize to ring spectra. This gives rise to the trace map $\text{tr}: K(R) \to \text{THH}(R)$, where the target is the topological Hochschild homology first defined by Bökstedt [6]. The purpose of the present paper is to identify the composition

$$R : BGL_1(R) \to K(R) \to \text{THH}(R) \to \Omega^1(R) \quad (1.1)$$

when $R$ is a commutative ring spectrum. The first two arrows are defined for any (symmetric) ring spectrum, whereas the definition of the last map depends on $R$ being commutative. By definition, $\text{THH}(R)$ is the infinite loop space associated to the realization of the cyclic spectrum $[k] \ast R^\wedge(k+1)$ with Hochschild type structure maps. We shall use Bökstedt's explicit definition of the smash products $R^\wedge(k+1)$. If $R$ is commutative, the degree-wise multiplication $R^\wedge(k+1) \to R$ defines a map to the constant cyclic spectrum. This gives rise to the infinite loop map $r$ in the definition of $R$.

In order to state our main result, we need the fact that $GL_1(R)$ has the structure of an infinite loop space when $R$ is commutative, i.e., that there exists a spectrum $\text{gl}_1(R)$ such that $\Omega^1(\text{gl}_1(R)) \to GL_1(R)$. (We follow the convention to use small letters for the spectrum associated to an infinite loop space written in capital letters.) It will be convenient for our purpose to give an explicit construction of $\text{gl}_1(R)$ using Segal's notion of $\Gamma$-spaces. Let $2 \ast (S^0)$ denote the stable Hopf map.

**Theorem 1.2** The composite map $R$ admits a factorization

$$BGL_1(R) \to GL_1(R) \to \Omega^1(R),$$

in which the second map is the natural inclusion and the first map is multiplication by $r$ in the sense of the following commutative diagram in the homotopy geometry topology, Volume 8 (2004)
category of spaces,

\[ \xymatrix{ B \text{GL}_1(R) \ar[r]^\beta & \text{GL}_1(R) \ar[d]^\gamma \\
\Omega^1 (\text{gl}_1(R) \wedge S^1) \ar[r]^{\Omega^1 (\text{id}^\ast)} & \Omega^1 (\text{gl}_1(R)) } \]

In the case where \( R \) equals the sphere spectrum this result is due to Bökstedt and Waldhausen [8] (with a completely different proof).

It is clear from the definition that there is an isomorphism of abelian groups \( \text{id} \) for \( i = 1 \), but since the spectrum structures are different this is not an isomorphism of \( S^0 \)-modules. However, using that \( \text{id} \) is realized as an unstable map \( : S^3 \to S^2 \), it is not difficult to check that the actions of are compatible in degrees \( i = 2 \). The following is then an immediate corollary of Theorem 1.2.

**Corollary 1.3** For \( i = 3 \), the composition

\[ i_{-1} R = iB \text{GL}_1(R) \to iK(R) \to i \text{THH}(R) \to iR \]

is multiplication by \( 2 \). This implies that classes in \( i_{-1} R \) not annihilated by \( i \) give rise to non-trivial elements in \( iK(R) \).

**Example 1.4** Let \( R = \text{ko} \), the real connective K-theory spectrum. In this case \( \text{GL}_1(\text{ko}) \) is \( \text{gl}_1(\text{ko}) \) that \( \otimes \) indicates that the H-space structure is the one corresponding to tensor products of vector bundles. Using the co-bration sequence \( \text{ko} \to \text{ko} \to \text{ku}, \text{ko} \to \text{ku} \), [18, V.5.15], we see that

\[ Z = \text{ko}! \quad \text{ko}_1 = Z=2 \]

is surjective and that

\[ Z=2 = \text{ko}! \quad \text{ko}_2 = Z=2 \]

is an isomorphism. We conclude that for \( k = 1 \),

\[ 8k+1 \text{BBO}_\otimes = Z \text{ maps non-trivially to } 8k+1 K(\text{ko}); \]
\[ 8k+2 \text{BBO}_\otimes = Z=2 \text{ injects as a direct summand in } 8k+2 K(\text{ko}). \]
This example is interesting in view of the attempts [1], [2], to relate algebraic K-theory to elliptic cohomology and the chromatic filtration of homotopy theory. Another major source for the interest in algebraic K-theory in the non-linear setting is the relation to high dimensional manifold theory via Waldhausen's work on stable concordances [20].

**Example 1.5** Let \( R = (G, +) \) be the suspension spectrum of a commutative (or \( E_1 \)) group-like monoid \( G \). By definition, the algebraic K-theory of this spectrum is Waldhausen's \( A(BG) \). In this case, \( _iBGL_1(R) = _i(G, +) \), and thus classes in the stable homotopy that are not annihilated by \( m \) map non-trivially to \( _iA(BG) \) in degrees \( i > 3 \).

**Remark 1.6** Given a discrete ring \( R \), the algebraic K-theory of the associated Eilenberg-MacLane spectrum \( H \mathbb{R} \) reduces to Quillen's \( K(\mathbb{R}) \). Starting with a ring spectrum \( R \) and \( R = \mathbb{R} \), the linearization map \( R \to H \mathbb{R} \) gives rise to a fibration sequence

\[
F \to K(R) \to K(\mathbb{R});
\]

whereby definition \( F \) is the homotopy fibre. Let \( SL_1(R) \) be the unit component of \( GL_1(R) \). Using that \( BSL_1(R) = \) we get a map \( BSL_1(R) \to F \) which is important in the understanding of how algebraic K-theory behaves under linearization.

The proof of Theorem 1.2 breaks up into two parts. The first part is to give a description of \( R \) in non-K-theoretical terms as the composition

\[
BGL_1(R) \to \text{L}(BGL_1(R)) \to B^{\infty}GL_1(R) \overset{r}{\to} GL_1(R) \to \Omega^1(R);
\]

Here \( \text{L}(BGL_1(R)) \) denotes the free loop space of \( BGL_1(R) \) and \( B^{\infty}GL_1(R) \) is Waldhausen's cyclic bar construction, see Section 3. The first map is the inclusion of the constant loops and the map \( r : B^{\infty}GL_1(R) \to GL_1(R) \) is given by iterated multiplication in \( GL_1(R) \). The fact that \( GL_1(R) \) is an infinite loop space ensures that it is sufficiently homotopy commutative for the latter map to be well-defined.

The second part of the proof is then to show that the composite map \( BGL_1(R) \to GL_1(R) \) is multiplication by \( 1 \). This follows from a general analysis of how the free loop space of an infinite loop space relates to the cyclic bar construction. Let us say that a sequence of maps of based spaces \( F \to X \to Y \) is a homotopy fibre sequence if (i) the composition is constant and (ii) the canonical map from \( F \) to the homotopy fibre of the second map is a weak homotopy equivalence. (This definition is most useful if \( Y \) is connected.) Given a

well-pointed group-like topological monoid $G$, there is a commutative diagram of homotopy fibrations

$$
\begin{array}{c}
G \\
\uparrow \text{y} \\
\Omega(BG) \\
\downarrow \text{y} \\
L(BG) \\
\downarrow \\
BG;
\end{array}
$$

in which the lower sequence is split by the inclusion of the constant loops $BG \to L(BG)$. If furthermore $G$ admits the structure of an infinite loop space, then the upper sequence has a natural splitting $B^\otimes G \to G$ given by the iterated product in $G$. The failure of these splittings to be compatible is measured by the fact that the composition

$$BG \to L(BG) \to B^\otimes G \to G$$

is multiplication by $\text{y}$ in the sense described above for $\text{GL}_1(R)$.

The paper is as a whole fairly self-contained, and in particular we present in Section 4 a new explicit construction of the trace map $\text{tr}: K(R) \to \text{THH}(R)$. This version of the trace map is used here to identify the action on $\text{BGL}_1(R)$, but there are many other applications of this combinatorial construction. In Section 2 we recall the definition of symmetric ring spectra and their units and in Section 3 we recall Waldhausen's definition of algebraic $K$-theory in this framework. The Sections 2-4 can be read as a self-contained account of the topological trace map.

In Section 5 we explain the infinite loop structure of $\text{GL}_1(R)$ used in the formulation of Theorem 1.2, and in Section 6 we construct the splitting $r: \text{THH}(R) \to \Omega^2(R)$ and complete the first part of the proof. Finally, in Section 7 we consider the relationship between the free loop space and the cyclic bar construction of an infinite loop space and finish the second part of the proof.

### 1.1 Notation and conventions

Let $T$ be the category of based spaces. In this paper this can be understood as either the category of compactly generated Hausdorff (or weak Hausdorff) topological spaces or the category of based simplicial sets. However, we will usually use the topological terminology and talk about topological monoids etc. In both cases equivalences mean weak homotopy equivalences. In the topological case we will sometimes have to assume that base points are non-degenerate in the usual sense of being neighborhood deformation retracts.
We let $S^n$ denote the $n$-fold smash product of the circle $S^1 = \mathbb{I} = @I$. By a spectrum $E$ we understand a sequence $f_{E_n}: n \to S^n$ of based spaces together with based maps $: S^n \wedge E_n ! E_{n+1}$. Again this may be interpreted either in the topological or simplicial category. A map of spectra $f : E \to F$ is a sequence of based maps $f_n : E_n ! F_n$ that commute with the structure maps. We say that $f$ is an equivalence if it induces an isomorphism on spectrum homotopy groups, the latter being defined by $nE = \lim_{k \to \infty} n+k E_k$. All spectra we consider will be connective, i.e., $nE = 0$ for $n < 0$. We shall also assume that the spectra we consider are convergent in the sense that there exists an unbounded, non-decreasing sequence of natural numbers $f_n : n \to 0$ such that $S^n \wedge E_n ! E_{n+1}$ is at least $n + n$-connected for all $n$. This is not a serious restriction as any connective spectrum is equivalent to a convergent one.

## 2 Units of ring spectra

In this section we recall Waldhausen’s definition of the space of units associated to a ring spectrum. We shall work in the framework of symmetric spectra and begin by recalling the relevant definitions from [12] and, for the version with topological spaces instead of simplicial sets, [16].

### 2.1 Symmetric spectra

A symmetric spectrum is a spectrum in which each of the spaces $E_n$ is equipped with a base point preserving left $n$-action, such that the iterated structure maps

$$m : S^m \wedge E_n \to E_{m+n}$$

are $m \wedge n$-equivariant. A symmetric ring spectrum is a symmetric spectrum equipped with $n$-equivariant maps $1_n : S^n \to E_n$ for $n \geq 0$, and $m \wedge n$-equivariant maps $m,n : E_m \wedge E_n \to E_{m+n}$ for $m,n \geq 0$. In order to formulate the axioms, let $n$ be the composite

$$n : E_m \wedge S^n \to S^n \wedge E_m \to E_{n+m} \to E_{m+n};$$

where $tw$ twists the two factors, and $n,m$ is the $(n;m)$-shuffle map $i \wedge i + m$ for $i \leq n$, $i \wedge i - n$ for $i > n$. Notice that $n$ is $m \wedge n$-equivariant. Also, let $0 : S^0 \wedge E_n \to E_n$ and $0 : E_n \wedge S^0 \to E_n$ be the canonical identifications. These maps are required to satisfy the following relations for all $l,m,n \geq 0$:

(a) $1_{m+n} = m(S^m \wedge 1_n),$
Units of ring spectra and their traces in algebraic K-theory

\[(b) \quad m = m; n \quad (1_m \wedge E_n); \quad n = m; n \quad (E_m \wedge 1_n),\]

\[(c) \quad l + m; n \quad (l; m \wedge E_n) = l; m + n \quad (E_l \wedge m; n).\]

Here condition (a) states that the maps \(1_n\) assemble to give a map of spectra \(1: S \to E\), where \(S\) denotes the sphere spectrum. Notice that (b) and (c) imply that

\[l; m + n \quad (E_l \wedge m) = l + m; n \quad (m \wedge E_n)\]

as maps \(E_l \wedge S^m \wedge E_n \to E_{l+m+n}\) and that

\[l \quad (S^l \wedge m; n) = l + m; n \quad (l \wedge E_n);\]

These are exactly the conditions for the maps \(m; n\) to produce a map of spectra \(E^l : E \wedge E \to E\), where the domain is the internal smash product in the category of symmetric spectra. Condition (b) then says that 1 is a two-sided unit, and (c) is the condition that the multiplication is associative. (These comments on the internal smash product are only to motivate the definitions; we shall not make explicit use of the internal smash product in this paper.) We say that \(R\) is commutative if the diagrams

\[
\begin{array}{ccc}
R_m \wedge R_n & \xrightarrow{m \wedge n} & R_{m+n} \\
\gamma & \circ & \gamma \\
R_n \wedge R_m & \xrightarrow{m \wedge n} & R_{n+m}
\end{array}
\]

are commutative.

### 2.2 \(I\)-spaces and \(I\)-monoids

In order to define the units of a symmetric ring spectrum we need a combinatorial framework to keep track of the suspension coordinates. Let \(I\) be the category whose objects are the finite sets \(n = f1; \ldots; ng \) and whose morphisms are the injective (not necessarily order preserving) maps. The empty set \(0\) is an initial object. The concatenation \(m \cdot n\) is defined by letting \(m\) correspond to the first \(m\) elements and \(n\) to the last \(n\) elements of \(f1; \ldots; m + ng\). The structure of a symmetric monoidal category. The symmetric structure is given by the shuffles \(m; n\) : \(m \cdot n \to n \cdot m\).

We define an \(I\)-space to be a functor \(X: I \to \mathcal{T}\). Given an \(I\)-space \(X\), we write \(X_{ht}\) = hocolim \(X\). The homotopy type of \(X_{ht}\) can be analyzed using the following lemma due to Bökstedt. For published versions see [15, 2.3.7] and [9, 2.5.1]. Let \(F_n I\) be the full subcategory of \(I\) containing the objects of cardinality at least \(n\).
Lemma 2.1 (Bökstedt) Let $X$ be an $I$-space and suppose that each morphism $n_1 \rightarrow n_2$ in $F_n I$ induces an $n$-connected map $X(n_1) \rightarrow X(n_2)$. Then, given any object $m$ in $F_n I$, the natural map $X(m) \rightarrow X_{hl}$ given by the inclusion in the $0$-skeleton is at least $(n-1)$-connected.

Let us say that an $I$-space $X$ is convergent if there exists an unbounded, non-decreasing sequence of natural numbers $f: n \rightarrow \mathbb{N}$ such that any morphism $n_1 \rightarrow n_2$ in $F_n I$ induces a $n$-connected map $X(n_1) \rightarrow X(n_2)$. It follows from Bökstedt’s lemma that in this case $X_{hl}$ is equivalent to the usual telescope of the sequence of spaces $X(n)$ obtained by restricting to the natural subset inclusions in $I$. In particular, $X_{hl}$ is the usual directed colimit of the groups $X(n)$ if $X$ is convergent.

We say that an $I$-space $X$ is an $I$-monoid if it comes equipped with an associative and unital natural transformation

$$m; n: X(m) \times X(n) \rightarrow X(m + n);$$

where both sides are considered functors on $I^2$. The unital condition means that the basepoint in $X(0)$ acts as a unit and associativity means that the identity

$$l; m + n (X_l m; n) = l + m; n (l; m X_n)$$

holds for all $l; m; n \in 0$. By definition an $I$-monoid $X$ is commutative if the diagrams

$$X(m) \otimes X(n) \xrightarrow{m; n} X(m + n)$$

are commutative. If $X$ is an $I$-monoid, then $X_{hl}$ inherits the structure of a topological monoid. The product is given by the composition

$$X_{hl} \otimes X_{hl} = \text{hocolim} X(m) \otimes X(n) \rightarrow \text{hocolim} X(m + n) \rightarrow X_{hl},$$

in which the last map is induced by the monoidal structure of $I$. We say that $X$ is group-like if this is the case for $X_{hl}$, i.e., if the monoid of components $0X_{hl}$ is a group. We will show in Section 5 that if $X$ is commutative and group-like, then $X_{hl}$ has the structure of an infinite loop space.

Remark 2.2 For $I$-spaces $X$ that are not convergent, the homotopy type of $X_{hl}$ may well differ from that of the usual telescope. Consider for example the $I$-monoid $n \not\rightarrow B_n$. In this case the associated homotopy colimit is equivalent.
to the base point component of $\mathbb{Q}(S^0)$. To see this one uses that the natural map $B \xrightarrow{1} \operatorname{hocolim} B_n$ induces an isomorphism on integral homology. By the universal property of Quillen's plus-construction and the fact that the target is a connected $H$-space, it follows that the latter is equivalent to $B \xrightarrow{\mathbb{1}}$. The conclusion then follows from the Barratt-Priddy-Quillen-Segal Theorem. As a second example, let $R$ be a discrete ring and consider the $I$-monoid defined by the classifying spaces $BGL_n(R)$. By an argument similar to the above, the associated homotopy colimit is equivalent to the base point component of the algebraic $K$-theory space $K(R)$. In these examples (and many more), evaluating the homotopy colimit over $I$ thus has the same effect as Quillen's plus-construction.

### 2.3 Units of ring spectra

Given a symmetric ring spectrum $R$, the sequence of spaces $\Omega^n(R_n)$ defines an $I$-space as follows. A morphism $m ! n$ in $I$ induces a map $\Omega^m(R_m) \to \Omega^n(R_n)$ by taking $f \to 2 \Omega^m(R_m)$ to the composition

$$S^n \xrightarrow{\mathbb{1}^{-1}} S^n = S^l \cup \mathbb{Z}^m S^l \cup \mathbb{Z} S^l R_m \to R_n \to R_n : (2.3)$$

Here $m = \text{lt } m ! n$ is the unique permutation that is order preserving on the first $l = n - m$ elements and acts as on the last $m$ elements. The action on $S^n$ is the usual left action. The multiplication in $R$ gives a multiplicative structure

$$m_n : \Omega^m(R_m) \times \Omega^n(R_n) ! \Omega^{m+n}(R_{m+n});$$

$$m_n(f; g) : S^m \cup S^n \xrightarrow{f \cup g} R_m \cup R_n \to R_{m+n};$$

which is commutative if $R$ is. We let $\Omega^n(R_n)$ be the union of the components in $\Omega^n(R_n)$ that have stable multiplicative homotopy inverses in the following sense: For each $f$ in $\Omega^n(R_n)$ there exists an element $g \in 2 \Omega^n(R_m)$ such that $m_n(f; g)$ and $m_n(g; f)$ are homotopic to the unit $1_{m+n}$ in $\Omega^{m+n}(R_{m+n})$. We consider $\Omega^n(R_n)$ as a based space with base point $1_n$, and restricting the above structure maps gives an $I$-monoid $\Omega^n(R_n)$. We define

$$GL_1(R) = \operatorname{hocolim}_I \Omega^n(R_n)$$

with the monoid structure explained above. If $R$ is convergent so is the $I$-space $\Omega^n(R_n)$, and by Lemma 2.1, $\Omega_0(GL_1(R)) = GL_1(\mathbb{0}(R))$. If furthermore $R$ is commutative, the general construction in section 5 will produce a spectrum $gl_1(R)$ such that $\Omega^1(gl_1(R)) = GL_1(R)$.
3 K-theory and cyclic K-theory of ring spectra

In this section we recall the definition of the algebraic K-theory $K(R)$ and the cyclic algebraic K-theory $K^c(R)$ of a symmetric ring spectrum $R$. We also recall the inclusion of the units $B GL_1(R)! K(R)$. This material is due mainly to Waldhausen. Let $M_n(R)$ be the symmetric ring spectrum whose $m$th space is $\text{Map}(n_+; n_+ ^+ R_m)$. The multiplication resembles multiplication of $n \times n$ matrices over an ordinary ring. (In this case the matrices in question have at most one non-base point entry in each column.) We let $GL_n(R) = GL_1(M_n(R))$ with the monoid structure coming from the multiplication in $M_n(R)$. Using the natural maps

$$\text{Map}(m_+ ^+ S^k; m_+ ^+ R_k) \text{ Map}(n_+ ^+ S^l; n_+ ^+ R_l)$$

$$\text{! Map}((m \uplus n)_+ ^+ S^{k+l}; (m \uplus n)_+ ^+ R_{k+l})$$

we have a notion of block sum of matrices and corresponding monoid homomorphisms

$$GL_m(R) \text{ GL}_n(R) \text{ GL}_{m+n}(R):$$

These homomorphisms are associative in the obvious sense and thus the induced maps of classifying spaces give $\text{Map}(n_0 B GL_n(R))$ the structure of an associative topological monoid. By definition $K(R)$ is the group completion

$$K(R) = \Omega B^{a \text{ GL}_n(R)}: n_0$$

Notice that this is the version of algebraic K-theory with $\text{0}_R K(R) = \mathbb{Z}$.

The classifying space of the units $B GL_1(R)$ embeds in the 1-simplices of $B (n_0 B GL_n(R))$ and since there is just a single 0-simplex there is an induced map

$$S^1 \text{ B GL}_1(R)_+ \text{ B GL}_n(R)$$

whose adjoint is the requested map $B GL_1(R) ! K(R)$. The image is contained in the 1-component of $K(R)$.

There is a variant of all this using the cyclic bar construction $B^c GL_n(R)$. Recall that for a topological monoid $G$, $B^c G$ is the realization of the cyclic space $[k] \forall G^{k+1}$ with simplicial operators

$$d_i(g_0; \ldots; g_k) = (g_0; \ldots; g_{i+1}; \ldots; g_k); \text{ for } 0 \leq i < k$$

$$d_k(g_0; \ldots; g_{k-1}); \text{ for } i = k$$

$$s_i(g_0; \ldots; g_k) = (g_0; \ldots; g_i 1; \ldots; g_k); \text{ for } 0 \leq i \leq k$$
and cyclic operator $t_k(g_0, \ldots, g_k) = (g_k, g_0, \ldots, g_{k-1})$. We refer the reader to [13] for background material on cyclic spaces. The degree-wise projections $(g_0, \ldots, g_k) \mapsto (g_k, g_0, \ldots, g_{k-1})$ define a simplicial map $p: B^\Omega G \to B G$, and if $G$ is group-like and has a non-degenerate unit there results a homotopy fibration sequence

$$G \to B^\Omega G \to B G.$$

Since $B^\Omega G$ is a cyclic space its realization has a canonical action of the circle group $\mathbb{T}$. Consider the composite map $\mathbb{T} \to B^\Omega G \to B^\Omega G$ induced by $\mathbb{T}$-action. Letting $L(-)$ denote the free loop space, the adjoint is a map $B^\Omega G \to L(B G)$. It is immediate from the definition that this is a $\mathbb{T}$-equivariant map when the action on $L(B G)$ is by multiplication in $\mathbb{T}$. The following proposition is well-known and follows easily from the definition of the $\mathbb{T}$-action. We shall prove a related result in Proposition 7.1 with a proof that can easily be adapted to the present situation.

**Proposition 3.1** There is a commutative diagram

$$
\begin{array}{ccc}
G & \xrightarrow{i} & B^\Omega G \\
\downarrow & & \downarrow p \\
\Omega(B G) & \xrightarrow{\alpha} & L(B G) \\
\end{array}
$$

in which the lower sequence is the usual fibration sequence associated to the evaluation at the unit element of $\mathbb{T}$. If $G$ is group-like and has a non-degenerate unit, then the upper sequence is a homotopy fibration sequence and the vertical maps are equivalences.

Notice that the lower sequence in (3.1) is split by the inclusion of $B G$ in $L(B G)$ as the constant loops. By definition the cyclic $K$-theory of a symmetric ring spectrum $R$ is given by

$$K^\Omega(R) = \Omega B^\Omega GL_n(R).$$

The projections $p: B^\Omega GL_n(R) \to B GL_n(R)$ induce a map $p: K^\Omega(R) \to K(R)$ which has a section in the homotopy category. The quickest way to see this is to consider the diagram of monoid homomorphisms

$$
\begin{array}{ccc}
B GL_n(R) & \xrightarrow{a} & L(B GL_n(R)) \\
\downarrow n & & \downarrow n \\
B^\Omega GL_n(R) & \xrightarrow{a} & B^\Omega GL_n(R) \\
\end{array}
$$

where the equivalence is a consequence of Proposition 3.1. After group completion there results a well-defined homotopy class $K(R) \to K^\Omega(R)$, giving a section of $p$ up to homotopy.

*Geometry & Topology, Volume 8 (2004)*
4 Topological Hochschild homology and the trace map

In this section we present an explicit construction of the topological trace map $\text{tr}: K(R) \to \text{THH}(R)$, where the target is the topological Hochschild homology. In order to motivate the construction we first recall the linear trace map $\text{tr}: K(R) \to \text{HH}(R)$ with target the Hochschild homology of $R$. The latter is the realization of a cyclic abelian group $\text{HH}(R): [k] \to R \otimes k + 1$ with cyclic structure maps similar to $B^\circ \text{G}$. The multi-trace $\text{tr}: \text{HH}(M_n(R)) \to \text{HH}(R)$ is the cyclic map given in degree $k$ by

$$\text{tr}(A^0 \otimes \cdots \otimes A^k) = \bigoplus_{s_0, \ldots, s_k} a_{s_k, s_0}^0 \otimes a_{s_{k-1}, s_k}^1; \text{ where } A^i = (a_{s,t}^i):$$

Composing with the obvious inclusions $B^\circ \text{GL}_n(R) \to \text{HH}(M_n(R))$ we get a cyclic map

$$\text{a \ : \ B^\circ \text{GL}_n(R) \to \text{HH}(M_n(R)) \to \text{HH}(R):}$$

This is a monoid homomorphism with respect to block-sums of matrices on the domain and the abelian group structure on the target. After realization and group completion we get maps

$$K^\circ(R) \to \Omega \text{HH}(R) \to \text{HH}(R):$$

The linear trace map $\text{tr}: K(R) \to \text{HH}(R)$ is the homotopy class obtained by composing with the homotopy section $K(R) \to K^\circ(R)$.

4.1 Topological Hochschild homology

Topological Hochschild homology is obtained by replacing the tensor products in $\text{HH}(R)$ by smash products of spectra. We shall follow Bökstedt [6] in making this precise. Given a sequence of symmetric spectra $E^1, \ldots, E^r$, we consider the smash product as a multi-indexed spectrum in the natural way,

$$(E^1 \wedge \cdots \wedge E^r)_{n_1, \ldots, n_r} = E_{n_1}^1 \wedge \cdots \wedge E_{n_r}^r;$$

In general an $r$-fold multi-indexed symmetric spectrum $E = f E_{n_1, \ldots, n_r} g$ has an associated infinite loop space

$$\Omega^1(E) = \text{hocolim}_{i \in \mathbb{Z}} \Omega^{n_1+} \cdots \Omega^{n_r} E_{n_1, \ldots, n_r}:$$

The functoriality underlying this definition is analogous to that in (2.3). We shall always use the symbol $\Omega^1(E)$ in this precise way. Notice that the monoidal structure of $I^r$ makes $\Omega^1$ a functor from multi-indexed spectra to topological monoids. The topological Hochschild homology of a ring spectrum $R$ is the topological realization of the cyclic spectrum $\text{TH}(R)$, defined in spectrum degree $n$ by

$$\text{TH}(R; n): [k] \mapsto \Omega^1(R \wedge \{ \wedge \} \wedge S^n):$$

The spectrum structure maps are defined in the obvious way involving only the $S^n$-factor. This construction represents Bökstedt’s solution to the problem of how to turn the multi-indexed spectrum $R^k$ into an equivalent singly-indexed spectrum. The cyclic structure maps are analogous to those in $B^\Omega(G)$ and $HH(R)$. Thus for example $d_0: \text{TH}_1(R) \to \text{TH}_0(R)$ is the composition

$$\text{hocolim}_I \Omega_0^{kn_1+n_1}(R_{n_0} \wedge R_{n_1} \wedge S^n)! \to \text{hocolim}_I \Omega_0^{kn_0+n_1}(R_{n_0+n_1} \wedge S^n)$$

where the first map uses the multiplication in $R$ and the second map is induced by the monoidal structure $t:I \wedge I \to I$. It follows from the version of Bökstedt’s approximation Lemma 2.1 with $I^{k+1}$ instead of $I$ that $\text{TH}(R)$ is an $\Omega$-spectrum, and we let $\text{THH}(R)$ be the 0th space.

In order to define the spectrum level multi-trace, we need to model the additive structure of a spectrum in a very precise way. We next explain how this can be done.

### 4.2 The cyclic Barratt-Eccles construction

Let $E_n$ be the cyclic set $[k] \not\sim _n k+1$ with simplicial operators

$$d_i ( \underline{0; \cdots; k} ) = ( \underline{0; \cdots; i-1}; i+1; \cdots; k); \quad 0 \leq i \leq k;$$

$$s_i ( \underline{0; \cdots; k} ) = ( \underline{0; \cdots; i-1}; i; i+1; \cdots; k); \quad 0 \leq i \leq k;$$

and cyclic operator $t_k ( \underline{0; \cdots; k} ) = ( k; 0; \cdots; k-1).$ We let $E^1_n$ be the cyclic Barratt-Eccles operad with $n$th space $E_n$, see [3], [17, 6.5]. This is an $E_1$ operad in the sense that the realization $E_n$ of the $n$th space is $n$-free and contractible. We use the notation $E^1_n$ for the associated functor from based spaces to simplicial based spaces,

$$E^1_n(X) = \wedge_n E_n X^n; \quad (4.1)$$
where the equivalence relation is defined as follows. Notice first that the correspondence \( m \not\in E \not\in n \) defines a contravariant functor from \( I \) to simplicial sets: Given a morphism : \( m! \not\in n \) in \( I \) and \( 2 \not\in n \), the composition has a unique factorization \( = ( ) ( ) \) with \( ( ) : m! \not\in n \) injective and order preserving and \( ( ) 2 \not\in m \). In this way, it induces a simplicial map, \( \not\in m \not\in ! E \not\in m; (0; \ldots ; k) \not\in (0; \ldots ; k) \) and given : \( I ! m \) it is clear that \( ( ) = ( ) \). Secondly, given a based space \( X \) the correspondence \( n \not\in X \not\in n \) defines a covariant functor on \( I \) by letting a morphism : \( m! \not\in n \) act on \( x \in X \) by \( (x) = y \), where

\[
y_j = \begin{cases} x_i; & \text{if } (i) = j \\ ; & \text{if } j \not\in (m) \\
\end{cases}
\]

With this notation, the equivalence relation in (4.1) is generated by the relations

\[
(e; (x)) \sim \not\in (e; x) \quad \text{for } e 2 E \not\in k; x 2 X m \quad \text{and} \quad m! \not\in n:
\]

In other words, \( E^1 (X) \) is the tensor product of the functors \( n \not\in E \not\in n \) and \( n \not\in X \not\in n \) over \( I \), i.e., the coend of the \( I \not\in \text{op}\) \(-\)-diagram \( E \not\in m \not\in X \not\in n \), cf. [14, IX.6]. We let \( E^1 (X) \) be the realization. (Barratt and Eccles use the notation \( \Gamma^n(X) \), but we want to avoid this since we also use \( \Gamma \)-spaces in the sense of Segal.) We write the elements of \( E^1 (X) \) as \( [; x] \) where \( 2 E \not\in k \) and \( x 2 X k \). Block sums of permutations give \( E^1 (X) \) the structure of a simplicial topological monoid,

\[
[; x] [0, x^0] = [0, (x; x^0)]
\]

The homotopy theoretical significance of the functor \( E^1 (X) \) is that it provides a combinatorial model of \( \Omega^1 \not\in \not\in X \) for non-degenerately based connected \( X \). In more detail, it is proved in [3] that in the diagram

\[
E^1 (X) ! \colim \Omega^n E^1 (S^n \not\in X) \rightarrow \colim \Omega^n (S^n \not\in X);
\]

the left hand arrow is an equivalence for connected \( X \) and the right hand arrow is an equivalence in general.

We extend \( E^1 \) to a functor on (symmetric) spectra by applying it in each spectrum dimension, i.e., \( E^1 (E) _n = E^1 (E) _n \) with structure maps

\[
S^1 \not\in \not\in E^1 (E) _n ! E^1 (S^1 \not\in E) _n ! E^1 (E) _{n+1}:
\]

Since we assume spectra to be connective and convergent, it easily follows that the natural map \( E ! E^1 (E) \) is an equivalence. Similarly, given a simplicial spectrum, we may apply \( E^1 \) degree-wise to get a bisimplicial spectrum and then restrict to the simplicial diagonal. This is in effect what we shall do when defining the spectrum level multi-trace.
4.3 The spectrum level multi-trace

The multi-trace for a symmetric ring spectrum $R$ is a natural map of multi-indexed spectra

$$\text{tr}: \bigwedge_{k+1} M_n(R)^k \to \bigwedge_{k+1} (R^k)^{\bigwedge M_n(R)}; \quad (4.2)$$

Let us first explain how to define this when $R$ is a spectrum of based simplicial sets. In this case $\text{tr}$ is based on a natural transformation

$$\text{tr}: M_n(X_0) \wedge X_k \to E_1^k (X_0 \wedge X_k);$$

where $X_0; \ldots; X_k$ are based sets and $M_n(X_i) = \text{Map}(n_+; n_+ \wedge X_i)$. Suppose given an element $(A_0; \ldots; A_k)$ in the domain and use matrix notation to write

$$A_i = (x_{s_0}^{i}; \ldots; x_{s_k}^{i})$$

Let $D$ be the set of multi-indices corresponding to the non-trivial summands in the multi-trace formula, i.e,

$$D = f(s_0; \ldots; s_k): x_{s_k}^{0} \notin \cdots \notin x_{s_k}^{k}; x_{s_k-1}^{0} \notin \cdots \notin x_{s_k-1}^{k};$$

Since by definition the matrices have at most one non-base point entry in each column, the projections $(s_0; \ldots; s_k) \notin s_i$ give rise to injective maps $p_i: D \to m$. Suppose that $D$ has cardinality $m$ and order the elements by choosing a bijection $\gamma: m \to D$. The composition $p_\gamma: m \to D$ is injective for each $i$ and admits a unique factorization $p_\gamma = p_i$, where $p_i$ is injective and order preserving and $1 \leq \gamma \leq m$. Consider the natural map

$$D \to X_0 \wedge X_k; \quad (s_0; \ldots; s_k) \mapsto (x_{s_k}^{0}; \ldots; x_{s_k}^{k})$$

and let $x$ be the composition

$$x: m \to D \to X_0 \wedge X_k;$$

The first observation is that the element

$$[(0; \ldots; k); x] \mapsto \bigwedge_{m} (X_0 \wedge X_k)^m$$

is independent of the ordering $\gamma$ used to define it. By definition the multi-trace is the image in $E_1^k (X_0 \wedge X_k)$, i.e,

$$\text{tr}(A^0; \ldots; A^k) = [(0; \ldots; k); x] \mapsto \bigwedge_{k+1} (X_0 \wedge X_k); \quad (4.3)$$

The second observation is that because of the base point relations in the target this construction is natural with respect to based maps in $X_0; \ldots; X_k$.

Example 4.4 As an example to illustrate the construction we calculate

$$\text{tr} x_0^2 x_1^2; x_0^2 x_1^2 = [(1_2); (x_0^2; x_1^2); (x_0^2; x_1^2)];$$

where $2_2$ is the non-identity element.
The spectrum level multi-trace (4.2) is defined by degree-wise extending the above natural transformation to a natural transformation between functors of simplicial sets. We then extend this to a natural transformation of multi-indexed spectra by applying it in each multi-degree. This gives the required maps

$$\text{tr}: M_n(R_{n_0}) \wedge \wedge M_n(R_{n_k}) \rightarrow \varepsilon_1^k (R_{n_0} \wedge \wedge R_{n_k})$$

In the case where $R$ is a spectrum of topological spaces we observe that the expression in (4.3) also makes sense if $X_0, \ldots, X_k$ are (non-degenerately) based topological spaces, and we define $\text{tr}$ by the same formula.

### 4.4 The topological trace map

We define a combinatorially enriched version $TH^+(R)$ of topological Hochschild homology by applying Bökstedt's construction to the multi-indexed spectrum on the right hand side of (4.2), i.e.,

$$TH^+(R; n): [k] \nabla \Omega^1 \left( \varepsilon_1^k (R \wedge \wedge R)^{S^n} \right)$$

This is in a natural way the cyclic diagonal of a bicyclic spectrum. The $+$ decoration indicates that $TH^+(R; n)$ is a homotopy commutative cyclic monoid. Using the natural inclusion $X \nabla \varepsilon_1 (X)$ we get a degree-wise equivalence $TH (R) \rightarrow TH^+(R)$ and thus an equivalence of realizations $TH(R) \rightarrow TH^+(R)$.

The spectrum level multi-trace has formal properties similar to the linear multi-trace and in particular there results a cyclic map

$$\text{tr}: TH (M_n(R)) \rightarrow TH^+(R);$$

(One can show that the realization can be extended to give an equivalence of $T$-equivariant spectra, but we shall not use this here.) The definition of the topological trace map is now completely analogous to the linear case. There is an obvious embedding of cyclic spaces $\text{B}^{\mathcal{O}^\vee}GL_n(R) \rightarrow THH (M_n(R))$ induced by the natural transformation

$$\Omega^{n_0} (M_n(R_{n_0})) \rightarrow \Omega^{n_0} (M_n(R_{n_k})) \rightarrow \Omega^{n_0+} (M_n(R_{n_0}) \wedge \wedge M_n(R_{n_k}))$$

that sends a tuple of maps to their smash product. Composing with the multi-trace we get a cyclic map

$$a: \text{B}^{\mathcal{O}^\vee}GL_n(R) \rightarrow THH (M_n(R)) \rightarrow THH^+(R);$$

$$a: n_0 \rightarrow n_0$$

This is a monoid homomorphism with respect to block sums of matrices on the domain and the simplicial monoid structure on the target. After realization and group completion we get maps

\[ K^\mathcal{O}(R) \to \Omega B(\text{THH}^+(R)) \to \text{THH}^+(R) \to \text{THH}(R). \]

The topological trace map \( \text{tr}: K(R) \to \text{THH}(R) \) is the homotopy class obtained by composing with the homotopy section \( K(R) \to K^\mathcal{O}(R) \).

**Remark 4.6** It is not difficult to extend this definition of the trace map to a map of spectra or to refine it to a version of the cyclotomic trace \( \text{trc}: K(R) \to \text{TC}(R) \), cf. [7]. However, this is not the purpose of the present paper. A construction of the trace map from a more categorical point of view has been given by Dundas and McCarthy [11] and Dundas [10].

Letting \( n = 1 \) in (4.5) gives a map \( B^\mathcal{O}\text{GL}_1(R) \to \text{THH}(R) \). The following proposition is immediate from the definitions

**Proposition 4.7** There is a strictly commutative diagram of spaces

\[
\begin{array}{ccc}
B^\mathcal{O}\text{GL}_1(R) & \longrightarrow & \text{THH}(R) \\
\nearrow & & \nearrow \\
K^\mathcal{O}(R) & \longrightarrow & \Omega B\text{THH}^+(R) \\
\end{array}
\]

\hspace{1cm} (4.8)

5 \( \Gamma \)-spaces and units of commutative ring spectra

In this section we show that if \( R \) is a commutative (and convergent) ring spectrum, then \( \text{GL}_1(R) \) is the 0th space of an \( \Omega \)-spectrum. The same is true for the group-like monoid \( X_{hI} \) associated to a commutative and group-like \( I \)-monoid \( X \), and we formulate the construction in this generality.

5.1 \( \Gamma \)-spaces

We first recall Segal's notion of \( \Gamma \)-spaces and the Anderson-Segal method for constructing the associated homology theory. The paper by Bousfield and Friedlander [4] is the basic reference for this material. Let \( \Gamma^o \) denote the category of finite pointed sets and pointed maps. A \( \Gamma \)-space is a functor \( A: \Gamma^o \to T \) such that \( A(\emptyset) = 1 \). We say that a \( \Gamma \)-space is special if given pointed sets \( S \) and \( T \) the natural map \( A(S) \times A(T) \to A(S \times T) \) is an equivalence. This
implies in particular that $A(S^0)$ has the structure of a homotopy associative and commutative H-space with multiplication

$$A(S^0) \to A(S^0 \wedge S^0) \to A(S^0):$$

We say that $A$ is very special if $A(S^0)$ is group-like, i.e., if the monoid of components is a group. A $\Gamma$-space $A$ extends to a functor on the category of pointed simplicial sets in a two stage procedure. First $A$ is extended to the category of all pointed sets by forcing it to commute with colimits. Given a simplicial set $X$ we then apply $A$ degree-wise to get a simplicial space $A(X)$ with realization $A(X)$. The main result is that if $A$ is very special then the resulting functor is a homology theory: Applying $A$ to a cofibration sequence of pointed simplicial sets $X \to Y \to Y = \Sigma X$ gives a homotopy cofibration sequence

$$A(X) \to A(Y) \to A(Y = \Sigma X)$$

in the sense that the inclusion of $A(X)$ in the homotopy fiber of the second map is an equivalence. In particular, a very special $\Gamma$-space gives rise to a symmetric $\Omega$-spectrum $f A(S^n) : n \geq 0$, in which the structure maps are the realizations of the obvious (multi-)simplicial maps $S^1 \wedge A(S^n) \to A(S^{n+1})$.

### 5.2 $\Gamma$-spaces associated to commutative $I$-monoids

In order to motivate the construction we recall the definition of the $\Gamma$-space associated to a commutative topological monoid $G$. Given a finite based set $S$, let $|S|$ be the subset obtained by excluding the base point. Then $G(S) = G|S|$, and a based map $: S \to T$ induces a map $G(S) \to G(T)$ by multiplying the elements in $G$ indexed by $-1$ for each $t \in T$.

Implementing this idea for a commutative $I$-monoid requires some preparation. Given $S$ as above, let $P(S)$ be the category of subsets and inclusions in $S$. A based map $: S \to T$ induces a functor $P(T) \to P(S)$ by letting $U \to U$ for $U \to S$. The category $D(S)$ of $S$-indexed sum diagrams in $I$ as follows. An object is a functor $P(S) \to I$ that takes disjoint unions to coproducts of finite sets, i.e., if $U \to V = \cdot$, then the diagram $U \to V \cdot V$ represents $U \wedge V$ as a coproduct of finite sets. (The category $I$ itself does of course not have coproducts.) Notice in particular that $\cdot = 0$. A morphism in $D(S)$ is a natural transformations of functors (not necessarily an isomorphism). This construction is clearly functorial in $\Gamma^0$: A based map $: S \to T$ induces a functor $D(S) \to D(T)$ by letting $\cdot = \cdot$. Notice that an object in $D(S)$ is determined by its values $s$ for $s \in S$. 

a choice of injective map \( s \to U \) whenever \( s \not\subset U \) such that the induced map \( t_{s \subset U} \to U \) (with any ordering of the summands) is a bijection. Restricting to the one-point subsets of \( S \) gives a functor \( S : D(S) \to I^S \), where the latter denotes the product category indexed by \( S \) (we let \( I \) denote the one-point category). This is an equivalence of categories, and specifying an ordering of \( S \) gives a canonical choice of an inverse functor \( I^S \to D(S) \), using the monoidal structure of \( I \). Notice however, that \( I^S \) is not functorial in \( \Gamma \) as is the case for \( D(S) \).

**Lemma 5.1** Given a functor \( Y : I^S \to T \), the natural map
\[
\hocolim_{D(S)} Y_s \to \hocolim_{I^S} Y
\]
induced by \( S \) is an equivalence.

**Proof** By the co-naility criterion in [5, XI.9.2] (or rather its dual version) it suffices to check that for any object \( a \in I^S \), the category \((a \# S)\) of objects under \( a \) is contractible. But this is clear since this category has an initial object. 

Let now \( X \) be a commutative \( I \)-monoid and consider the \( I^S \)-diagram \( X^S \) defined by
\[
fS : s \subset S \to Y \to X(\eta_s):
\]
For \( S = \emptyset \) this should be interpreted as the one-point space. We use the notation \( X(S) \) for the \( D(S) \)-diagram obtained by composing with \( S \). With this definition \( X(S) \) is functorial in \( S \) in the sense that a based map \( : S \to T \) gives rise to a natural transformation of \( D(S) \)-diagrams
\[
X(S) \to X(T)
\]
In order to see this, choose an object \( t \) in \( D(S) \) and choose an ordering of the subsets \( U_t = -1(t) \) for each \( t \in T \). The map in question is then a product over \( T \) of maps of the form
\[
Y \to X(\eta_s) \to X(U_t)
\]
where the first arrow comes from the multiplication in \( X \) and the second arrow is induced by the bijection \( t_{s \subset U_t} \to U_t \) determined by the sum diagram. The main point is that since \( X \) is commutative the composite map does not depend on the ordering of \( U_t \) used to define it.
By definition the \( \Gamma \)-space associated to \( X \) is given by

\[
X_{hl}(S) = \text{hocolim}_{D(S)} X(S):
\]

Given a based map \( S \to T \), the induced map \( X_{hl}(S) \to X_{hl}(T) \) is the composition

\[
\text{hocolim}_{D(S)} X(S) \to \text{hocolim}_{D(T)} X(T) \to \text{hocolim}_{D(T)} X(T);
\]

where the first map is induced by the above natural transformation and the second map is the map of homotopy colimits determined by the functor.

It follows immediately from the definition that \( X_{hl}(S^0) = X_{hl} \). In order to compare \( X_{hl}(S^1) \) to the usual bar construction of \( X_{hl} \) we specify an ordering of the \( k \)-simplices in \( S^1 \) by letting

\[
u_j = (0; \ldots; 0; 1; \ldots; 1);
\]

for \( j = 0; \ldots; k \): \hspace{1cm} (5.2)

Then \( u_0 \) is the base point and \( S^1_k = f u_1; \ldots; u_k \).

Proposition 5.3 The \( \Gamma \)-space associated to a commutative \( I \)-monoid \( X \) is always special and is very special if and only if the underlying monoid \( X_{hl} \) is group-like. In general there is a natural equivalence \( B X_{hl} \to X_{hl}(S^1) \).

Proof Using Lemma 5.1 we get an equivalence

\[
X_{hl}(S) = \text{hocolim}_{D(S)} X(S) \to \text{hocolim}_{I^S} X(S) = \bigvee_{s \in S} X_{hl}(S);
\]

which is the condition for \( X_{hl} \) to be special. The statement about being very special follows from the definition. In order to define the equivalence we use the ordering of the simplices of \( S^1 \) given by (5.2). As noted earlier this ordering determines an equivalence

\[
\text{hocolim}_{I^k} X(n_1) \to X(n_k) \to \text{hocolim}_{D(S^1_k)} X(S^1_k)
\]

using the monoidal structure of \( I \). Identifying the left hand side with the \( k \)-simplices of \( B X_{hl} \) we get a simplicial map \( B X_{hl} \to X_{hl}(S^1) \). Since this is an equivalence in each simplicial degree its realization is also an equivalence as required.
Remark 5.4 This construction of Γ-spaces based on the category $\mathcal{D}(S)$ differs from that of Segal [19, x2] in that we allow all natural transformations, not only the natural isomorphisms. Consequently, our definition of the Γ-space associated to a commutative $I$-monoid takes into account all the maps $X(m) \rightarrow X(n)$ induced by morphisms in $I$. As an example, consider the commutative $I$-monoid given by the classifying spaces $BO(n)$ of the orthogonal groups. In this case Segal’s construction produces a special Γ-space with underlying space $BO(n)$, whereas our construction produces a very special Γ-space with underlying space $\text{hocolim} BO(n) \rightarrow BO$. The last equivalence follows from Bökstedt's Lemma 2.1. Thus the two constructions respectively produce models of the $(-1)$-connected and 0-connected topological K-theory spectrum.

Definition 5.5 Given a commutative (and convergent) symmetric ring spectrum $R$, let $GL_1(R)$ be the Γ-space associated to the $I$-monoid $\Omega^n(R_n)$ considered in Section 2.3, and let $gl_1(R)$ be the associated spectrum.

It will always be clear from the context whether $GL_1(R)$ denotes a Γ-space as above or the underlying group-like monoid as in Section 2.

6 Commutative ring spectra and splittings

Let $R$ be a commutative symmetric ring spectrum. In this section we show that the natural inclusions $GL_1(R) \rightarrow BGL_1(R)$ and $\Omega^1(R) \rightarrow \text{THH}(R)$ have compatible left inverses in the homotopy category, where by compatible we mean that these splittings are related by a homotopy commutative diagram

\[
\begin{array}{ccc}
BGL_1(R) & \xrightarrow{f} & GL_1(R) \\
\downarrow \quad \downarrow & & \downarrow \quad \downarrow \\
\text{THH}(R) & \xrightarrow{g} & \Omega^1(R)
\end{array}
\] (6.1)

We then define $R$ to be the composite homotopy class

\[ R : BGL_1(R) ! K(R) \xrightarrow{f} \text{THH}(R) ! \xrightarrow{g} \Omega^1(R) : \]

Using the diagrams (4.8) and (6.1) we get an alternative description as follows.

Proposition 6.2 The homotopy class $R$ is represented by the composition

\[ BGL_1(R) ! L(BGL_1(R)) \xrightarrow{\approx} BGL_1(R) ! GL_1(R) ; \]

(where the first map is the inclusion of the constant loops), followed by the inclusion of $GL_1(R)$ in $\Omega^1(R)$. 

This concludes the first part of the proof of Theorem 1.2. In order to motivate the construction, consider the cyclic bar construction of a commutative monoid $G$. In this case the inclusion $G \to B^O G$ is split by degree-wise multiplication in $G$. This can also be expressed in terms of the $\Gamma$-space associated to $G$: The sequence $G \to B^O G \to BG$ is the effect of evaluating $G$ on the cofibration sequence $S^0 \to S^1 \to S^1$, and the splitting is induced by the projection $S^1 \to S^0$ that maps $S^1$ to the non-base point in $S^0$. Let now $GL_1(R)$ be the $\Gamma$-space defined in Definition 5.5. The next Lemma shows that we may replace $B^O GL_1(R)$ by $GL_1(R)(S^1_+)$ up to homotopy.

**Proposition 6.3** Let $X$ be a convergent and commutative $I$-monoid. Then there exists a space $W^O$ and equivalences

$$B^O_{\text{hl}} X^I \simeq W^O_{\text{hl}} X (S^1_+).$$

**Proof** Let $W^O$ be the cyclic space

$$[k] \mapsto \lim_{\longleftarrow} X(n_0 \cdot t^0) \cdot X(n_k \cdot t^k);$$

where $i$ is an object of $D(S^1_+)$ and we write $i = u_0$. We have functors $I^k \cdot I^k \to D(S^1_+)$ obtained by fixing the initial object in one of the factors. The cyclic structure of $W^O$ is the obvious one such that the induced maps

$$B^O_{\text{hl}} X^I \simeq W^O_{\text{hl}} X (S^1_+)$$

become maps of cyclic spaces. Since we assume that $X$ is convergent, it follows from Bökstedt's approximation lemma 2.1 (with $I^{k+1}$ instead of $I$), that these maps are equivalences in each simplicial degree. After realization we thus get a pair of equivalences relating $B^O_{\text{hl}} X^I$ and $X (S^1_+)$. 

**Remark 6.4** The condition that $X$ be convergent is necessary for the argument in Proposition 6.3, since otherwise the map

$$\lim_{\longleftarrow} X (m) \to \lim_{\longleftarrow} X (m \cdot t^0)$$

induced by the functor $I^k \cdot I^k$, $m \not= (m; 0)$ need not be an equivalence. The $I$-monoid $X (n) = X^n$ considered in Section 4 provides a counter example. It should also be noted that the construction of the simplicial map $B X_{\text{hl}} \to X_{\text{hl}} (S^1)$ in the proof of Proposition 5.3 cannot be applied to give a cyclic map $B^O_{\text{hl}} X^I \to X_{\text{hl}} (S^1_+)$. 

Using the above equivalences, we define the splitting $r$ to be the composite homotopy class

$$r: B^\otimes \text{GL}_1(R) \to \text{GL}_1(R);$$

where the last map is induced by the projection $S^1_0 \to S^0$.

We next consider a version $\text{TH}^0(R)$ of topological Hochschild homology that relates to $\text{TH}(R)$ as $\text{GL}_1(R)(S^1_0)$ relates to $B^\otimes \text{GL}_1(R)$. By definition this is the realization of the cyclic spectrum

$$\text{TH}^0(R; n): [k] \not\to \text{hocolim}_{D(S^1_0)} \Omega^0 \otimes R_0 \otimes \cdots \otimes R_k \otimes S^n;$$

where $\otimes$ denotes an object in $D(S^1_0)$ and we again write $i = u_i$. The cyclic structure maps are defined as for $\text{GL}_1(R)(S^1_0)$. For example, in spectrum degree zero, $d_0: \text{THH}_0^0(R) \to \text{THH}_0^0(R)$ is the composition

$$\text{hocolim}_0 \otimes R_0 \otimes R_1 \otimes \cdots \otimes R_k \otimes S^n;$$

Here $0^1_0$ denotes an object in $D(S^1_0)$ and the first map is induced by the natural transformation that takes $f: 2 \Omega^0 \otimes R_0 \otimes R_1$ to the element in $\Omega^0_0(R_0)$ given by the composition

$$S^1_0 \otimes 1 \otimes S^1_0 \otimes i \otimes R_0 \otimes R_1 \otimes \cdots \otimes R_k \otimes S^n;$$

where $: 0^1_0 \otimes 1$ is the bijection determined by $i$. The second map is induced by the natural transformation $d_0: D(S^1_0) \to D(S^1_0)$. With this definition we have the equality

$$d_0 = d_1: \text{THH}_0^0(R) \to \text{THH}_0^0(R)$$

and consequently the iterated boundary maps give a well-defined cyclic map $r: \text{TH}^0(R) \to \text{THH}_0^0(R)$, where the target is considered a constant cyclic spectrum. In spectrum degree zero we thus get a cyclic map of spaces

$$r: \text{THH}^0_0(R) \to \Omega^1_0(R);$$

The next proposition is the analogue of Proposition 6.3.

**Proposition 6.5** The spectra $\text{TH}(R)$ and $\text{TH}^0(R)$ are related by a pair of equivalences.

**Proof** Letting $W^\otimes = fW^\otimes(n): n \to g$ denote the cyclic spectrum

$$[k] \not\to \text{hocolim}_{D(S^1_0)} \otimes R_0 \otimes \cdots \otimes R_k \otimes S^n;$$

the proof proceeds exactly like the proof of Proposition 6.3. □
As in the definition of the trace map we consider the transformation

\[ \Omega^0(R_0) \rightarrow \Omega(R_0) \rightarrow \Omega^t_k(R_0 \wedge R_0) \]

that sends a tuple of maps to their smash product. Viewing these maps as natural transformations of \( D(S^1_k) \)-diagrams we get a cyclic map

\[ \text{GL}_1(R)(S^1_+) \rightarrow \text{THH}^0(R); \]

It follows immediately from the definitions that this map is compatible with the splittings of \( B\text{GL}_1(R) \) and \( \text{THH}^0(R) \) in the sense of the following proposition.

\textbf{Proposition 6.6} There is a strictly commutative diagram of spaces

\[
\begin{array}{ccc}
\text{GL}_1(R)(S^1_+) & \rightarrow & \text{GL}_1(R) \\
\downarrow & \searrow & \downarrow \\
\text{THH}^0(R) & \rightarrow & \Omega^1(R) \\
\end{array}
\]

The homotopy commutative diagram (6.1) in the beginning of this section is derived from this using the equivalences in Proposition 6.3 and Proposition 6.5.

\section{The Hopf map and free loops on infinite loop spaces}

In this section we finish the proof of Theorem 1.2 by showing that the composite homotopy class

\[ B\text{GL}_1(R) \rightarrow L(B\text{GL}_1(R)) \rightarrow B\Omega\text{GL}_1(R) \rightarrow \text{GL}_1(R) \]

is multiplication by \( \gamma \) in the sense explained in the introduction. More generally, let \( G \) be a very special \( \Gamma \)-space and let \( g = f(G(S^n)) \). Evaluating \( \gamma \) on the based cyclic set \( S^1_+ \) gives a cyclic space \( G(S^1_+) \). The realization \( G(S^1) \) then has a \( T \)-action and, as in the case of the cyclic bar construction, we consider the composite map

\[ T \rightarrow G(S^1_+) \rightarrow G(S^1) \rightarrow G(S^1) \]

with adjoint \( G(S^1_+) \rightarrow L(G(S^1)) \). In the next proposition we analyze the homotopy bration sequence obtained by evaluating \( G \) on the bration sequence \( S^0 \rightarrow S^1 \rightarrow S^1 \).
Proposition 7.1 There is a commutative diagram of homotopy fibrations

\[
\begin{array}{ccc}
G(S^0) & \longrightarrow & G(S_1^1) \\
\uparrow & & \uparrow \\
\Omega(G(S^1)) & \longrightarrow & L(G(S_1^1))
\end{array}
\]

(7.2)

in which the vertical maps are equivalences.

Proof The commutativity of the right hand square is immediate since we evaluate a loop at the unit element of \(T\). In order to prove commutativity of the left hand square we recall that for any cyclic space \(X\), the \(T\)-action on the zero simplices \(X_0 = \{x \mid x \in X\}\) has the following description. If \(x\) is an element of \(X_0\) and \(u \in T\),

\[u \cdot x = [t_1 x; u] \in T_1 X\]

Here \(t_1\) is the cyclic operator in degree one and we make the identification \(T = \mathbb{Z} = \mathbb{R}\). Using this, it is easy to check that the composition

\[T \cdot G(S^0) \ll T \cdot G(S_1^1) \ll G(S_1^1) \ll G(S^1)\]

is given by \((u; x) \mapsto [x^0 u]\), where \(x^0 2 G(S_1^1)\) is the image of \(x\) under the homeomorphism induced by the based bijection \(S^0 \ll S_1^1\). The above composition clearly equals the composition

\[T \cdot G(S^0) \ll S_1^1 \cap G(S^0) \ll G(S^1)\]

which shows that the left hand square in the diagram is also commutative.

In Diagram (7.2) the map \(L(G(S_1^1)) \ll G(S^1)\) in the lower sequence is split by the inclusion of the constant loops, and the map \(G(S^0) \ll G(S_1^1)\) in the upper sequence is split by evaluating \(G\) on the projection \(r : S_1^1 \ll S^0\) that maps \(S^1\) to the non-base point of \(S^0\). The next proposition expresses the fact that these splittings are not compatible in general. As usual \(2 \cdot \Omega^1(S^0)\) denotes the stable Hopf map.

Proposition 7.3 Using the natural equivalences \(\Omega^1 (g^\wedge S^1) \ll G(S^1)\) and \(\Omega^1 (g) \ll G(S^0)\), the composite homotopy class

\[G(S^1) \ll L(G(S^1)) \ll G(S_1^1) \ll G(S^0)\]

is given by \(\Omega^1 (g^\wedge )\).
Proof. We first observe that (7.2) is in fact a diagram of infinite loop spaces and infinite loop maps, and that as such it is equivalent to the following diagram of spectra

\[
\begin{array}{ccc}
S^0 & \longrightarrow & S^1 \\
\gamma & \downarrow & \gamma \\
F(S^0; g^S) & \longrightarrow & F(S^1; g^S) \\
\end{array}
\]

Here \(F(\cdot; g^S)\) is the obvious function spectrum and the upper and lower co-bration sequences are both induced from \(S^0 \to S^1 \to S^1\). These co-bration sequences have canonical stable splittings induced by the projection \(r: S^1 \to S^0\) and the associated stable section \(s: S^1 \to S^1\). The vertical map in the middle is the adjoint of \(S^1 \times g^S\), \(g^S\), \(g^S\), \(g^S\);

where the first map uses the action of \(S^1\) on itself given by the group structure. It is clear that the above diagram is equivalent to the one obtained by smashing \(g\) with

\[
\begin{array}{ccc}
S^0 & \longrightarrow & S^1 \\
\gamma & \downarrow & \gamma \\
F(S^0; S^1) & \longrightarrow & F(S^1; S^1) \\
\end{array}
\]

Here the definition of is analogous to the definition given above. We must prove that the stable map

\[
S^1 = F(S^0; S^1) \to F(S^1; S^1), \quad S^1 \to S^0
\]

represents . Using the canonical splittings to represent \(-1\) as a 2x2 matrix, this composition represents the off diagonal term. It is therefore the negative of the composite stable map starting in the upper right corner of the diagram,

\[
S^1 \otimes S^1 \to F(S^1; S^1) \to F(S^0; S^1)
\]

The adjoint of this is the stable map

\[
S^1 \times S^1 \cong S^1 \times S^1 \to S^1 \to S^1
\]

where the second map is the group multiplication in \(S^1\). It is well-known that this composition represents . For example, one can see this by considering the equivariant splitting \(eS^1 \to S^1 \times S^1\), whose domain is the unreduced suspension of \(S^1\), and then use that the map of homotopy colimits induced by the diagram

\[
S^1 \to S^1 \to S^1
\]

represents a generator of $3(S^2)$, cf. [22, XI.4]. The result now follows since has order two.

**Proof of Theorem 1.2** The only thing left to prove is that the homotopy class $BGL_1(R) \to GL_1(R)$ considered in Proposition 6.2 agrees with the one in Proposition 7.3 when the $\Gamma$-space in question is $GL_1(R)$ and we use the canonical equivalence $BGL_1(R) \to GL_1(R)(S^1)$, cf. Proposition 5.3. Let $W$ be the realization of the simplicial space

$$[k] \cup \hocolim_{ D(S^k_\ell) } X(n_1 t \ldots t_1) \times X(n_1 t \ldots t_k);$$

Since the space $W^\gamma$ considered in Proposition 6.3 is the realization of a cyclic space it has a $\mathbb{T}$-action, and the adjoint of the composition $\mathbb{T} \to W^\gamma \to W$ gives an equivalence $W^\gamma \to L(W)$. It easily follows that we have a commutative diagram of equivalences

$$\begin{array}{ccc}
BGL_1(R) & \to & W^\gamma \\
? & \to & ? \\
L(BGL_1(R)) & \to & L(W)
\end{array} \quad \begin{array}{ccc}
GL_1(R)(S^1) & \to & GL_1(R)(S^1) \\
? & \to & ? \\
L(GL_1(R)(S^1)) & \to & L(GL_1(R)(S^1));
\end{array}$$

It thus succeeds to check that the homotopy class defined by the diagram

$$BGL_1(R) \to W \to GL_1(R)(S^1)$$

is compatible with the canonical equivalence $BGL_1(R) \to GL_1(R)(S^1)$. We do this by exhibiting an explicit homotopy inverse of the equivalence $GL_1(R)(S^1) \to W$. Let $W^0$ be the realization of the simplicial space

$$[k] \cup \hocolim_{ D(S^k_\ell) } X(n_1 t \ldots t_1) \times X(n_1 t \ldots t_k);$$

Ordering the $k$-simplices $S^k_\ell$ as in the proof of 5.3 gives an equivalence $W \to W^0$. Moreover, using the monoidal structure of $I$ we get a functor $D(S^k_\ell) \to D(S^k_\ell)$. Varying $k$ this is a transformation of simplicial categories and consequently there is an induced simplicial map $W^0 \to GL_1(R)(S^1)$. It is easy to check that the composition $W \to W^0 \to GL_1(R)(S^1)$ is a homotopy inverse of the map in question and that the composition with $BGL_1(R) \to W$ is the canonical equivalence. This completes the proof.

**Remark 7.4** The discussion in the above proof can be generalized to any commutative $I$-monoid $X$. If $X$ is convergent, $B^\gamma X_{hl}$ and $X_{hl}(S^1_\ell)$ are
related by cyclic equivalences as in Proposition 6.3, and if $X$ is group-like we get equivalences relating the same spaces by comparing them to the relevant free loop spaces. In case $X$ is both convergent and group-like, the two equivalences agree by an argument similar to the above.
