Abstract

Bound polysemy is the property of any pair (G_1, G_2) of graphs on a shared vertex set V for which there exists a partial order on V such that any pair of vertices has an upper bound precisely when the pair is an edge in G_1 and a lower bound precisely when it is an edge in G_2 . We examine several special cases and prove a characterization of the bound polysemic pairs that illuminates a connection with the squared graphs.

2000 *Mathematics Subject Classification*. Primary 05C62, 06A07.

1 Introduction

McMorris and Zaslavsky [9] define an *upper bound graph* as any graph whose vertices may be partially ordered in such a way that distinct vertices have an upper bound if and only if they are adjacent. This class of graphs has been studied widely [1, 2, 3, 4, 8] since its introduction. An excellent current survey of the field may be found in [7].

It is straightforward to see that the *lower bound graphs*, defined analogously, constitute precisely the same class. In general, a poset realizes two graphs simultaneously: one is its upper bound graph and another, its lower bound graph. These graphs may be thought of as two meanings of the poset, two answers to the question, “What is this poset trying to tell me?”

We call a pair of graphs $G_1 = (V, E_1)$ and $G_2 = (V, E_2)$ on a common vertex set *bound polysemic* provided there exists a partial order \leq on V such that distinct $u, v \in V$ have an upper bound in (V, \leq) if and only if $uv \in E_1$ and a lower bound if and only if $uv \in E_2$. If such a partial order exists, the poset (V, \leq) is called a *bound polysemic realization* of (G_1, G_2) .

Polysemic pairs of graphs are introduced in [12], which addresses intersection polysemy: the pairs of intersection graphs that arise from families of sets and of those sets’ complements. Notions of polysemy for posets are explored in [11] and [13].

Although they do not highlight the polysemy phenomenon, Lundgren, Maybee, and McMorris [6] and Bergstrand and Jones [2] investigate a closely related problem. Call a pair of graphs G_1 and G_2 for which $|V(G_1)| = |V(G_2)|$ *unlabeled bound polysemic* provided that they are isomorphic, respectively, to graphs H_1 and H_2 that

are themselves bound polysemic. A result in [6] amounts to a characterization of the unlabeled bound polysemic pairs. In some contexts where it is important to contrast it with unlabeled bound polysemy, we refer to bound polysemy as *labeled*.

Consider the morphisms that carry adjacency in the graphs to boundedness (above and below, respectively) in the poset, and assume without loss of generality that the graphs have the same vertex set. In the case of unlabeled polysemy, the two morphisms are independent of one another, whereas in the labeled case a single morphism does double duty. We think of the two cases in terms of labeling because if one tagged the vertices with their images under these morphisms, precisely the labeled case would result in a consistent assignment of tags.

We present here a characterization of the labeled bound polysemic pairs, which hints at a connection to the squared graphs. The remainder of this section gives some basic definitions. Section 2 surveys several results by way of background. Section 3 discusses known results for unlabeled bound polysemy. Section 4 addresses several special cases of bound polysemy. Section 5 proves more general results, including our characterization of the bound polysemic pairs. And Section 6 concludes with some open problems.

All graphs considered here are finite and simple. The *open neighborhood* of a vertex v in a graph (V, E) is the set $N(v) = \{u \in V \mid uv \in E\}$, and the *closed neighborhood* is the set $N[v] = N(v) \cup \{v\}$. A *clique* in a graph is any complete induced subgraph and need not be maximal with that property. Cliques are often identified with their vertex sets. A vertex v is *simplicial* in some graph provided that $N(v)$ is a clique. An *edge clique cover* of a graph G is a set \mathcal{E} of cliques of G such that every edge uv of G , seen as a 2-set, is contained in some member of \mathcal{E} .

All posets $P = (X, \leq)$ considered here are finite and reflexive. Where several partial orders are being discussed, we sometimes append subscripts to their symbols, as \leq_P , to avoid ambiguity. The *height* of a poset is the maximum cardinality h of any chain $x_1 < x_2 < \cdots < x_h$ in the poset. A poset is *bipartite* provided that its height is at most 2. The *upset* of an element x in a poset $P = (X, \leq)$ is the set $X_{\geq}(x) = \{y \in X \mid y \geq x\}$. The set $\max(P)$ of *maximals* of P contains precisely those elements $x \in X$ for which $X_{\geq}(x) = \{x\}$. The *downset* $X_{\leq}(x)$ of x and the *minimals* $\min(P)$ of P are defined analogously. An element y of P *covers* another element x provided that $x < y$ and there exists no $z \in X$ with $x < z < y$.

The *dual* of a poset $P = (X, \leq)$ is the poset $P^d = (X, \geq)$ obtained by reversing the sense of every comparability of P . Poset duality runs throughout this topic: pairs of dual concepts include upsets and downsets, minimality and maximality, and boundedness above and below. And by dualizing posets we obtain an immediate proof that bound polysemy is a symmetric relation on the graphs with a given vertex set.

The *comparability graph* of a poset (X, \leq) has vertex set X and an edge xy for each comparability $x < y$. A poset is *connected* precisely when its comparability graph is connected. A *fence* is a poset whose comparability graph is a path.

For further definitions, notation, and background information, see for instance [14] and [15].

2 Background

Among the previous results that we use are four characterizations of the upper bound graphs. The first one is an easy observation. The other, more interesting, characterizations are taken from the literature.

Observation 1 *The upper (resp. lower) bound graph of a poset is exactly the intersection graph of the upsets (resp. downsets) of the poset.*

Theorem 2 (McMorris and Zaslavsky) *A graph is an upper bound graph if and only if it has an edge clique cover $\mathcal{E} = \{Q_1, \dots, Q_r\}$ for which there exists a system $\{v_1, \dots, v_r\}$ of distinct representatives such that $v_i \in Q_j$ precisely when $i = j$. \square*

The next characterization makes use of the notion of an *ordered edge cover* of a graph G —an edge clique cover $\{Q_1, \dots, Q_n\}$ of G together with a labeling $\{v_1, \dots, v_n\}$ of $V(G)$ such that each v_i is in Q_i and if $v_i \in Q_j$, then $i \leq j$ and $Q_i \subseteq Q_j$.

Theorem 3 (Lundgren and Maybee [5]) *A graph G is an upper bound graph if and only if it has an ordered edge cover. \square*

The proof of Theorem 2 proceeds by establishing a straightforward identity between the graph's distinct representatives and their corresponding cliques on the one hand, and the poset's maximals and their respective downsets on the other. In much the same way, Theorem 3 may be proven [6] by identifying the vertex labeling and cliques of the graph with a linear extension and all the downsets of the poset.

The third characterization was published independently in [1] and [3].

Theorem 4 (Bergstrand and Jones, Cheston et al.) *A graph is an upper bound graph if and only if each of its edges is in the closed neighborhood of some simplicial vertex. \square*

Another class of graphs that has been characterized in terms of edge clique covers is the squared graphs. A graph $G = (V, E)$ is *squared* provided that there exists a graph S on V such that $u, v \in V$ are adjacent in G if and only if $d_S(u, v) \leq 2$. Such a graph S is called a *square root* of G . This notion of multiplication is motivated by the identification of a graph with its adjacency matrix. Mukhopadhyay [10] characterized the squared graphs as follows.

Theorem 5 (Mukhopadhyay) *A graph on $V = \{v_1, \dots, v_n\}$ has a square root if and only if it has an edge clique cover $\mathcal{E} = \{Q_1, \dots, Q_n\}$ with the properties that*

1. for $1 \leq i \leq n$, $v_i \in Q_i$ and
2. for $1 \leq i < j \leq n$, $v_i \in Q_j$ if and only if $v_j \in Q_i$. \square

3 The Unlabeled Case

Recall that unlabeled bound polysemy consists in a pair of graphs that are isomorphic, respectively, to the upper and lower bound graphs of a single poset. Lundgren, Maybee, and McMorris [6] give a characterization of these pairs.

Theorem 6 (Lundgren, Maybee, and McMorris) *Given graphs G_1 and G_2 with the same number of vertices, the following are equivalent:*

1. G_1 and G_2 are unlabeled bound polysemic.
2. G_1 is (isomorphic to) the intersection graph of some ordered edge cover of G_2 .
3. G_2 is (isomorphic to) the intersection graph of some ordered edge cover of G_1 .
□

This result follows from Observation 1 and Theorem 3. Its third condition, for instance, translates to the assertion that G_1 has an upper bound realization whose downsets, under intersection, yield G_2 .

Bergstrand and Jones [2] provide the first examples of graphs that we would describe as unlabeled bound polysemic with themselves. A representative member G of one family of such graphs is shown in Figure 1. Any graph in this family consists

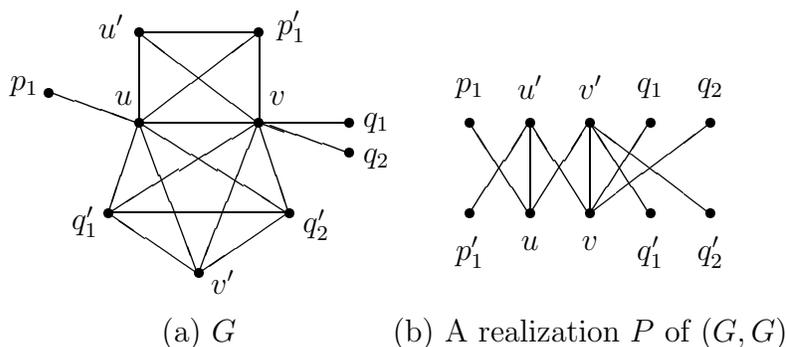

Figure 1: A graph that is unlabeled bound polysemic with itself

of cliques K_u and K_v that intersect in an edge uv and that each have at least one other vertex, together with $|K_u| - 3$ pendant vertices $p_1, \dots, p_{|K_u|-3}$ adjacent to u and $|K_v| - 3$ pendant vertices $q_1, \dots, q_{|K_v|-3}$ adjacent to v . It is clear that G is the upper bound graph of the poset P in Figure 1b: the annotation in the figure encodes the morphism carrying adjacency to boundedness above. And since P is isomorphic to its own dual, we have also that G is isomorphic to the lower bound graph of P . So P is an unlabeled bound polysemic realization of G .

Although G is unlabeled bound polysemic (with itself), it is not bound polysemic. To see this, consider any upper bound realization P' of G . Each of q_1 and q_2 must

have an upper bound in P' with v and with no other vertex, so each is comparable to v and to no other. Thus $v <_{P'} q_1, q_2$. But then v is a lower bound for q_1 and q_2 . So every lower bound graph of P' must include edge q_1q_2 , which G lacks. It follows that no upper bound realization of G is also a lower bound realization.

4 Special Cases of Labeled Bound Polysemy

We begin our investigation of (labeled) bound polysemy with results for several special cases. In contrast to the examples described in Section 3—graphs that are unlabeled bound polysemic with themselves—our first theorem characterizes the analogous class in the labeled case. In order to establish that characterization, we use the following lemma.

Lemma 7 *If a connected poset P has the property that any pair of elements has an upper bound if and only if it has a lower bound, then P has a maximum and a minimum.*

PROOF. Note that the connectedness of P implies that for any elements a and b of $P = (X, \leq)$ there is a fence $F = (Y, \leq_F)$ induced in P with a and b as its endpoints. We show by induction on the cardinality of F that there exist $\alpha_F, \omega_F \in X$ such that $\alpha_F \leq f \leq \omega_F$ for all $f \in F$. In particular, then, a and b have both an upper and a lower bound.

The base cases $|F| = 0, 1, 2$ are trivial. For the inductive step, let $|F| > 2$ and assume that b is minimal in F (the dual case may be argued analogously). Let $F' = F - b$ and consider $\alpha_{F'}, \omega_{F'} \in X$ as are guaranteed to exist by the inductive hypothesis. Since $b <_F f_i$ for some $f_i \in Y$, we also have $b < f_i \leq \omega_{F'}$, so b and $\alpha_{F'}$ have an upper bound. This means that they also have a lower bound α . So we choose $\omega_F = \omega_{F'}$ and $\alpha_F = \alpha$, and they have the required property.

Thus, every pair of elements of P has both an upper bound and a lower bound, so P must have a maximum and a minimum. ■

Theorem 8 *A graph is bound polysemic with itself if and only if it is a disjoint union of cliques.*

PROOF. It is straightforward to see that any disjoint union G of cliques is bound polysemic with itself. For each clique, construct a linear order on its vertices. Then the sum of these chains realizes (G, G) .

Conversely, let $G = (V, E)$ be any graph and P be a bound polysemic realization of (G, G) . It is clear that any pair of elements of P has an upper bound if and only if it has a lower bound, so by Lemma 7 distinct maximals (resp. minimals) must be in separate components of P . So G must be a disjoint union of cliques. ■

Corollary 9 *Every edgeless graph is bound polysemic with itself but with no other graph.*

PROOF. That $G = (V, \emptyset)$ is bound polysemic with itself follows immediately from Theorem 8. In particular, the only upper bound realization of G is the antichain on V , so it is clear that no graph on V with at least one edge is bound polysemic with G . ■

Theorem 10 *No graph with more than one vertex is bound polysemic with its complement.*

PROOF. Let $P = (V, \leq)$ be an upper bound realization of a graph $G = (V, E)$ with $n > 1$ vertices. If P is an antichain, then E is empty and the conclusion follows from Corollary 9. On the other hand, if there exist $u \leq v$ in P , then they have an upper bound, so $uv \in E$. But they have a lower bound, too, even though $uv \notin \overline{E}$. So no upper bound realization of G is also a lower bound realization of \overline{G} . ■

Theorem 11 *An n -vertex graph G is bound polysemic with K_n if and only if G is an upper bound graph with a vertex of degree $n - 1$.*

PROOF. Suppose G and K_n to be bound polysemic. We show that $\Delta(G) = n - 1$. Any lower bound realization of K_n has a minimum, since distinct minimals of a poset cannot have a lower bound and thus cannot be adjacent in a lower bound graph. But a minimum of a poset has an upper bound with every element, so the minimum of any realization of (G, K_n) has degree $n - 1$ in G .

Conversely, let G be an upper bound graph and suppose there exists a vertex v of degree $n - 1$ in G . If $G \cong K_n$, then the result follows from Theorem 8. Otherwise, v is not simplicial, so by Theorem 4 there exists an upper bound realization P' of $G - v$. Then the poset P obtained from P' by adding v as a minimum is an upper bound realization of G . And since v is a lower bound for every pair of elements, P is also a lower bound realization of K_n . ■

Theorem 12 *A graph $G = (V, E_G)$ is bound polysemic with a tree $T = (V, E_T)$ if and only if G is complete and T is a star.*

PROOF. Let T be a star and select $v \in V$ with degree $\Delta(T)$. Then the poset P for which $\min(P) = \{v\}$ and $\max(P) = V \setminus \{v\}$ is an upper bound realization of T . In the trivial case of $|V| = 2$, P and P^d are the only upper bound realizations of T . For $|V| \neq 2$, P itself is the only upper bound realization of T . This follows from the facts that no distinct $x, y \in V \setminus \{v\}$ can even have an upper bound—so they certainly cannot be comparable—and that if any x were incomparable to v , then x and v would have some upper bound $y \neq v$, which would imply $xy \in E(G)$. Note too that the lower bound graph of P , and of P^d in the case $|V| = 2$, is the complete graph on V .

Conversely, suppose T is not a star. Then $|V| = n \geq 4$, so T has a leaf u , and the neighbor v of u has degree strictly less than $n - 1$. Thus there exists $w \in V$ not adjacent to v and the u - w path has length at least 4, so T contains an induced P_4 . But neither vertex of the internal edge e of an induced P_4 can be simplicial, and T is K_3 -free. So e is not in the closed neighborhood of any simplicial vertex, and it follows from Theorem 4 that T is not an upper bound graph. ■

5 General Results

In their proof of Theorem 2, McMorris and Zaslavsky use a construction that demonstrates that any upper bound realization may be assumed without loss of generality to be bipartite. When we consider bound polysemy, the situation becomes only slightly more complicated. To begin with, take the example illustrated in Figure 2. It may

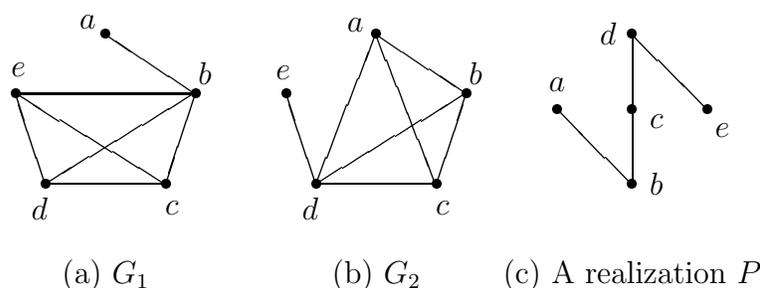

Figure 2: A bound polysemic pair with no bipartite realization

easily be verified that the poset P in Figure 2c is a bound polysemic realization of (G_1, G_2) , the pair in Figure 2a and b. How much flexibility does one have in constructing a realization of G_1 and G_2 ? Since neither c nor e is adjacent to a in G_1 and c is not adjacent to e in G_2 , $\{a, c, e\}$ must be an antichain. Furthermore, b must have lower bounds with each of a , c , and d , and it is the only element that can possibly be comparable to a . So b must be below the other three. Dually, d is the only element that can be comparable to e , and must be above b , c , and e . Thus, P is the unique bound polysemic realization of (G_1, G_2) , and, in particular, G_1 and G_2 have no bipartite realization.

Our next two results show that, while bound polysemic realizations of height less than 3 are something of a special case, height at most 3 may always be assumed.

Theorem 13 *A bound polysemic pair has a bipartite realization if and only if no triple of vertices induces a triangle in both graphs. Furthermore, if no such triple exists, then every realization is bipartite.*

PROOF. Let $G_1 = (V, E_1)$ and $G_2 = (V, E_2)$ be bound polysemic. It is a simple matter to verify that if some distinct $u, v, w \in V$ induce a triangle in both graphs, then no realization of (G_1, G_2) is bipartite. Contrapositively, if they have a bipartite realization, then no such triple exists.

On the other hand, if any realization $P = (V, \leq)$ has height at least 3, then there exist $u < v < w$ in V , so $\{u, v, w\}$ induces a triangle in each graph and every realization has height at least 3. ■

Theorem 14 For any poset $P = (X, \leq)$, let $P' = (X, \leq')$ be the height-3 poset for which

$$\leq' = \bigcup_{y \in \max(P)} \{(x, y) \mid x \leq y\} \cup \bigcup_{y \in \min(P)} \{(y, x) \mid x \geq y\}.$$

Then P and P' have the same upper bound graph and the same lower bound graph.

PROOF. It is clear that if $a, b \in X$ have an upper bound in P , then they have one that is maximal, so they also have an upper bound in P' . Conversely, any upper bound for elements a and b of P' is also an upper bound of a and b in P . So the two posets have the same upper bound graph and, dually, the same lower bound graph. ■

We now present our main result—a characterization of the bound polysemic pairs that blends the flavors of Theorems 2 and 5.

Theorem 15 Graphs $G_1 = (V, E_1)$ and $G_2 = (V, E_2)$ are bound polysemic if and only if there exist edge clique covers $\mathcal{E}_1 = \{Q_{1,1}, \dots, Q_{1,r}\}$ of G_1 and $\mathcal{E}_2 = \{Q_{2,1}, \dots, Q_{2,s}\}$ of G_2 and disjoint systems $R_1 = \{v_{1,1}, \dots, v_{1,r}\}$ and $R_2 = \{v_{2,1}, \dots, v_{2,s}\}$ of distinct representatives of \mathcal{E}_1 and \mathcal{E}_2 , respectively, with the properties that

1. $v_{k,i} \in Q_{k,j}$ precisely when $i = j$,
2. $\bigcup_{i=1}^r Q_{1,i} = \bigcup_{i=1}^s Q_{2,i}$, and
3. $Q_{1,i} \cap Q_{2,j}$ is nonempty only if $v_{1,i} \in Q_{2,j}$ and $v_{2,j} \in Q_{1,i}$.

PROOF. Property 1 is simply the necessary and sufficient condition in Theorem 2 for G_1 and G_2 to be (upper or lower) bound graphs, independent of one another. Properties 2 and 3 together with the requirement that the two systems R_1 and R_2 be disjoint give us the polysemy, as we now prove. Our approach is similar to the one used for Theorems 2 and 3—we establish for some poset $P = (V, \leq)$ the following identity:

$$\begin{aligned} R_1 &\leftrightarrow \max(P) \setminus \min(P) \\ Q_{1,i} &\leftrightarrow V_{\leq}(v_{1,i}) \\ R_2 &\leftrightarrow \min(P) \setminus \max(P) \\ Q_{2,i} &\leftrightarrow V_{\geq}(v_{2,i}) \end{aligned} \tag{1}$$

We begin by showing that the conditions are necessary for any realization P . Define \mathcal{E}_1 , \mathcal{E}_2 , R_1 , and R_2 as in (1). It is clear that R_1 and R_2 are disjoint. It also follows immediately, since \leq is reflexive and no maximal (resp. minimal) can be in the downset (resp. upset) of any other, that property 1 holds. Furthermore, $v \in V$ is in some downset in \mathcal{E}_1 (resp. upset in \mathcal{E}_2) only if v is not isolated in P , which, in turn, is the case only if v is in one of the upsets in \mathcal{E}_2 (resp. downsets in \mathcal{E}_1). So property 2 holds. And finally, if there exists any $v \in Q_{1,i} \cap Q_{2,j}$, then $v_{2,j} \leq v \leq v_{1,i}$; so property 3 holds by transitivity.

Conversely, suppose the edge clique covers \mathcal{E}_1 and \mathcal{E}_2 and their respective systems R_1 and R_2 of distinct representatives exist. We construct a bound polysemic realization $P = (V, \leq)$ of (G_1, G_2) by defining

$$\begin{aligned} \leq = & \bigcup_{i=1}^r \{(v, v_{1,i}) \mid v \in Q_{1,i}\} \cup \bigcup_{i=1}^s \{(v_{2,i}, v) \mid v \in Q_{2,i}\} \\ & \cup \{(v, v) \mid v \in V \setminus (R_1 \cup R_2)\}. \end{aligned} \tag{2}$$

It is clear from its definition and property 1 that \leq is reflexive. Property 1 also ensures that if $u \leq v$ and either $u \in R_1$ or $v \in R_2$, then $u = v$. So if both $u \leq v$ and $v \leq u$, then $u = v$. In other words, \leq is antisymmetric. Is it transitive? If there exist distinct $u, v, w \in V$ with $u \leq v$ and $v \leq w$, then $w \in R_1$ and $u \in R_2$. So $v \in Q_{1,i} \cap Q_{2,j}$, where $w = v_{1,i}$ and $u = v_{2,j}$. But then it follows from property 3 that $w \in Q_{2,j}$ and $u \in Q_{1,i}$, and either one of these memberships ensures that $u \leq w$. So \leq is a partial order.

It remains to demonstrate that G_1 and G_2 are the upper and lower bound graphs of P , respectively. We prove the case for G_1 —the other may be obtained from a dual argument. As a preliminary step, we prove that $\max(P) \setminus \min(P) \subseteq R_1$. The opposite containment is immediate, so the two sets are in fact equal. To see this, consider any nonminimal maximal v . There must exist $u \neq v$ for which (u, v) is a member of the first or second term of (2). If the comparability is in the first term, then $v \in R_1$ trivially. If the comparability appears in the second term only, then v is in some $Q_{2,i}$, so it follows from property 2 that v is also in some $Q_{1,j}$, and thus, from property 1 that $v = v_{i,j} \in R_1$.

Finally, is G_1 indeed the upper bound graph of P ? Any edge uv of G_1 is in at least one clique $Q_{1,i} \in \mathcal{E}_1$. As a result, u and v have $v_{1,i}$ as an upper bound in P . Conversely, if distinct $u, v \in V$ have an upper bound, then there exists $w \in \max(P) \setminus \min(P) = R_1$, say $w = v_{1,i}$, such that $u \leq w$ and $v \leq w$. If the comparability (u, w) is a member of the first term of (2), then $u \in Q_{1,i}$. Otherwise, the comparability is in the second term, so $u = v_{2,j}$ for some j and $w \in Q_{1,i} \cap Q_{2,j}$. Thus, by property 3, u is again in $Q_{1,i}$. By a parallel argument, v , too, is in $Q_{1,i}$, so u and v are adjacent in G_1 . ■

The similarity of the statements of Theorems 15 and 5 suggests that bound polysemic and squared graphs are related concepts. The connection between these concepts is captured in the following theorem.

Theorem 16 *If graphs $G_1 = (V, E_1)$ and $G_2 = (V, E_2)$ have a bound polysemic realization P that is bipartite, then $G_3 = (V, E_1 \cup E_2)$ is a squared graph with a square root equal to the underlying graph of the Hasse diagram of P .*

PROOF. We may call G_3 the *either bound graph* of P , since any distinct elements of V are adjacent in G_3 if and only if they have either an upper or a lower bound in P . It is immediate for any poset, regardless of height, that its comparability graph is a square root of its either bound graph. It only remains to demonstrate that the extra condition that P be bipartite is sufficient to ensure that the underlying graph H of the Hasse diagram of P is also a square root of G_3 .

Note that the closed neighborhood in H of any $w \in V$ is

$$N_H[w] = \begin{cases} V_{\leq}(w), & w \in \max(P) \\ V_{\geq}(w), & w \in \min(P) \end{cases}.$$

Note too that $d_H(u, v) \leq 2$ if and only if either (1) u and v are comparable, (2) they are minimals below some common maximal, or (3) they are maximals above some common minimal. But these three cases are equivalent, respectively, to (1') u and v have both an upper and a lower bound, (2') they have an upper bound, and (3') they have a lower bound. ■

The following theorem is a further parallel to a result from [9]. It shows that the bound polysemic pairs—like the upper bound graphs—cannot be characterized in terms of forbidden subgraphs.

Theorem 17 *For any graphs $G_1 = (V, E_1)$ and $G_2 = (V, E_2)$ on a common vertex set, there exists a bound polysemic pair $\{G'_1, G'_2\}$ such that G_1 is an induced subgraph of G'_1 and G_2 is an induced subgraph of G'_2 .*

PROOF. For any edge clique covers $\mathcal{E}_1 = \{Q_{1,1}, \dots, Q_{1,r}\}$ of G_1 and $\mathcal{E}_2 = \{Q_{2,1}, \dots, Q_{2,s}\}$ of G_2 , we enlarge our set of vertices to

$$V' = V \cup \{q_{1,1}, \dots, q_{1,r}\} \cup \{q_{2,1}, \dots, q_{2,s}\},$$

where none of the $q_{k,i}$ is in V . Next we define a partial order $P = (V', \leq)$, in which $\{q_{1,1}, \dots, q_{1,r}\}$, V , and $\{q_{2,1}, \dots, q_{2,s}\}$ are antichains and every $v \in V$ is covered by exactly those $q_{1,i}$ for which $v \in Q_{1,i}$ and covers exactly those $q_{2,i}$ for which $v \in Q_{2,i}$. Finally, let G'_1 and G'_2 be the upper and lower bound graphs, respectively, of P . Then G'_1 and G'_2 are bound polysemic by construction and each G_k is the subgraph of G'_k induced by V . ■

6 Open Problems

We have seen that $((V, \emptyset), (V, \emptyset))$, $(K_{1,n-1}, K_n)$, and the pair in Figure 2 each have a unique bound polysemic realization. Other such pairs may be obtained from the

graphs with unique upper bound realizations, which are characterized by McMorris and Myers [8]. It remains an open problem to completely characterize all the bound polysemic pairs that have unique representations.

An interesting algorithmic problem is the recognition of bound polysemy. Although Theorem 17 precludes one line of attack, Bergstrand and Jones [1] overcame an analogous situation, using Theorem 4 to obtain an $O(n^3)$ algorithm to recognize upper bound graphs.

Another open problem is the extension of our results by generalizing the posets to directed graphs. The analog of a poset's upper (resp. lower) bound graph is a digraph's *competition* (resp. *common enemy*) *graph*. It would be interesting to investigate what one might call *competition polysemy*.
