

## THE STRONG AMALGAMATION PROPERTY AND (EFFECTIVE) CODESCENT MORPHISMS

DALI ZANGURASHVILI

ABSTRACT. Codescent morphisms are described in regular categories which satisfy the so-called strong amalgamation property. Among varieties of universal algebras possessing this property are, as is known, categories of groups, not necessarily associative rings,  $M$ -sets (for a monoid  $M$ ), Lie algebras (over a field), quasi-groups, commutative quasi-groups, Steiner quasi-groups, medial quasi-groups, semilattices, lattices, weakly associative lattices, Boolean algebras, Heyting algebras. It is shown that every codescent morphism of groups is effective.

### 1. Introduction

Throughout the paper, we use “(effective) codescent morphism” to mean “(effective) codescent morphism with respect to the *basic fibration*”. Namely, let  $\mathcal{C}$  be a category with pushouts and let  $p : B \rightarrow E$  be its morphism. There is an adjunction

$$B/\mathcal{C} \begin{array}{c} \xleftarrow{p^!} \\ \xrightarrow{p_*} \end{array} E/\mathcal{C}$$

between coslice categories with the left adjoint  $p_*$  pushing out along  $p$  and the right adjoint  $p^!$  composing with  $p$  from right. The induced comonad on  $E/\mathcal{C}$  gives rise to the Eilenberg-Moore category of coalgebras (we denote it by  $\text{Codes}(p)$ ) equipped with the comparison functor

$$\Phi_p : B/\mathcal{C} \rightarrow \text{Codes}(p).$$

Recall that objects of  $\text{Codes}(p)$  (called codescent data with respect to  $p$ ) are triples  $(C, \gamma, \xi)$ , with  $C \in \text{Ob } \mathcal{C}$  and  $\gamma, \xi$  being morphisms  $E \rightarrow C$  and  $C \rightarrow C \sqcup_B E$ , respectively, such that the following equalities hold (see Figs.1 and 2):

$$\xi \gamma = \pi_2, \tag{1.1}$$

$$(1_C, \gamma)\xi = 1_C, \tag{1.2}$$

$$(\pi_1 \sqcup_B 1_E)\xi = (\xi \sqcup_B 1_E)\xi, \tag{1.3}$$

while the functor  $\Phi_p$  sends each  $f : B \rightarrow D$  to

$$(D \sqcup_B E, \pi'_2, \pi'_1 \sqcup_B 1_E),$$

where  $\pi'_1$  and  $\pi'_2$  are pushouts of  $p$  and  $f$ , respectively, along each other.

Fig. 1

Fig. 2

$p$  is called a codescent (effective codescent) morphism if  $\Phi_p$  is full and faithful (an equivalence of categories), i.e. if  $p_*$  is precomonadic (comonadic).

It is well-known that if  $\mathcal{C}$  is finitely cocomplete, then codescent morphisms are precisely couniversal regular monomorphisms, i.e. morphisms whose pushouts along any morphisms are regular monomorphisms [JT].

One of the goals of descent theory is to characterize (effective) codescent morphisms in particular varieties of universal algebras. There are several results obtained along this line. For instance, this problem has been completely solved for commutative rings with units (Joyal-Tierney (unpublished), [M]).

In this paper we describe codescent morphisms in those varieties of algebras (more generally, regular categories) which satisfy the strong amalgamation property and investigate the problem of the effectiveness of codescent morphisms in the case of groups.

Recall that the strong amalgamation property means that for any pushout square

$$\begin{array}{ccc} & m & \\ \alpha \downarrow & \square & \downarrow \alpha' \\ & m' & \end{array}$$

with monomorphisms  $m, \alpha$ , the morphisms  $m', \alpha'$  are also monomorphisms and, moreover, we have

$$\text{Im } m' \cap \text{Im } \alpha' = \text{Im } m'\alpha.$$

Among the varieties of universal algebras possessing this property are, as is known, categories of groups, not necessarily associative rings,  $M$ -sets (for a monoid  $M$ ), Lie algebras (over a field), quasi-groups, commutative quasi-groups, Steiner quasi-groups, medial quasi-groups, semilattices, lattices, weakly associative lattices, Boolean algebras, Heyting algebras. We show that a monomorphism  $p : B \rightarrow E$  of a variety of this kind is codescent if and only if

For any congruence  $R$  on  $B$  and its closure  $R'$  in  $E$  one has

$$R' \cap (B \times B) = R.$$

This in particular implies that every (regular) monomorphism of  $M$ -sets, semilattices, Boolean algebras and Heyting algebras is codescent. Note that the latter result related to the case of Boolean algebras was obtained earlier by Makkai (an unpublished work).

The main result of this paper asserts that

*Every codescent morphism of groups is effective.*

The author gratefully acknowledges useful discussions with George Janelidze on the subject of this paper.

## 2. The Strong Amalgamation Property and Codescent Morphisms

Before we begin our discussion, let us recall some definitions [KMPT].

Let  $\mathcal{C}$  be a category equipped with some proper factorization system  $(\mathbb{E}, \mathbb{M})$ , i.e., a factorization system which satisfies the conditions  $\mathbb{E} \subset \text{Epi } \mathcal{C}$  and  $\mathbb{M} \subset \text{Mon } \mathcal{C}$ .

$\mathcal{C}$  is said to satisfy the amalgamation (transferability; congruence extension) property if for each span

$$\begin{array}{ccc} & & m \\ & \searrow & \rightarrow \\ \alpha & \downarrow & \\ & & \end{array} \tag{2.1}$$

with  $m, \alpha \in \mathbb{M}$  ( $m \in \mathbb{M}$ ;  $m \in \mathbb{M}$  and  $\alpha \in \mathbb{E}$ ) there exists a commutative square

$$\begin{array}{ccc} & \xrightarrow{m} & \\ \alpha \downarrow & & \downarrow \alpha' \\ & \xrightarrow{m'} & \end{array} \tag{2.2}$$

with  $m', \alpha' \in \mathbb{M}$  ( $m' \in \mathbb{M}$ ;  $m' \in \mathbb{M}$ ).  $\mathcal{C}$  is said to satisfy the strong amalgamation property (the intersection property of amalgamation) if any span (2.1) with  $m, \alpha \in \mathbb{M}$  (any commutative diagram (2.2) with  $m, \alpha, m', \alpha' \in \mathbb{M}$ ) admits a pullback

$$\begin{array}{ccc} & \xrightarrow{m} & \\ \alpha \downarrow & & \downarrow \alpha'' \\ & \xrightarrow{m''} & \end{array} \tag{2.3}$$

with  $m'', \alpha'' \in \mathbb{M}$ . In the case of a variety  $\mathcal{C}$  of universal algebras and  $\mathbb{M} = \text{Mon } \mathcal{C}$ , this definition is equivalent to that of the strong amalgamation property given in the Introduction, as follows from the arguments given below.

Clearly,  $\mathcal{C}$  possesses the strong amalgamation property if and only if it satisfies both the amalgamation and the intersection property of amalgamation. If  $\mathcal{C}$  admits finite products, then the transferability property is equivalent to the amalgamation and congruence

extension properties <sup>2</sup>. The latter statement remains true if we replace “finite products” by “pushouts”. In that case all the definitions presented above can be reformulated. Namely, the amalgamation (transferability; congruence extension) property is equivalent to the requirement that the class  $\mathbb{M}$  be stable under pushouts along  $\mathbb{M}$ -morphisms (any morphisms;  $\mathbb{E}$ -morphisms), while the strong amalgamation property is satisfied if and only if the amalgamation property is fulfilled and pushout (2.2) is also a pullback square for any  $m, \alpha \in \mathbb{M}$ .

In what follows we make use of the following known result.

2.1. THEOREM. *Let  $\mathcal{C}$  admit pushouts. Then the following conditions are equivalent:*

- (i)  $\mathcal{C}$  satisfies the intersection property of amalgamation;
- (ii)  $\mathbb{M}$  consists of all regular monomorphisms.

*If, in addition,  $\mathcal{C}$  satisfies the amalgamation property, then each of (i), (ii) is equivalent to*

- (iii) every epimorphism lies in  $\mathbb{E}$ , and hence  $\mathbb{E} = \text{Epi } \mathcal{C}$ .

The implication (i) $\Rightarrow$ (ii) is obvious. (ii) $\Rightarrow$ (i) is proved in [K], [Ri], [T], while the equivalence (i) $\Leftrightarrow$ (iii) is proved in [Ri].

Most of investigations related to the question whether concrete categories satisfy the above-discussed properties deal with the case, where

$$\mathbb{M} = \text{all monomorphisms.} \tag{2.4}$$

From now on we shall follow assumption (2.4).

2.2. PROPOSITION. *Let  $\mathcal{C}$  be a regular category with pushouts and let  $\mathcal{C}$  satisfy the strong amalgamation property. Then the following conditions are equivalent for a monomorphism  $f : B \rightrightarrows E$  :*

- (i)  $f$  is a codescent morphism;
- (ii)  $f$  is a couniversal regular monomorphism;
- (iii)  $f$  is a  $\{\text{Regular epis}\}$ -couniversal regular monomorphism<sup>3</sup>;
- (iv)  $f$  is an  $\{\text{Epi}\}$ -couniversal monomorphism;

---

<sup>2</sup>We have to apply the transferability property to both “sides” and after that to take the product.

<sup>3</sup>Similarly to the notion of a couniversal regular monomorphism, for arbitrary morphism classes  $\mathcal{E}$  and  $\mathcal{M}$  one can define a  $\mathcal{E}$ -couniversal  $\mathcal{M}$ -morphism as a morphism whose pushout along any  $\mathcal{E}$ -morphism lies in  $\mathcal{M}$ .

(v) for any kernel pair  $R \rightrightarrows_{\alpha_2}^{\alpha_1} B$  on  $B$  and the kernel pair  $R' \rightrightarrows_{\alpha'_2}^{\alpha'_1} E$  of the coequalizer of  $(f\alpha_1, f\alpha_2)$ , the square

$$\begin{array}{ccc}
 R & \dashrightarrow & R' \\
 (\alpha_1, \alpha_2) \downarrow & & \downarrow (\alpha'_1, \alpha'_2) \\
 B \times B & \xrightarrow{f \times f} & E \times E
 \end{array} \tag{2.5}$$

is a pullback.

Each (regular) monomorphism of  $\mathcal{C}$  is a codescent morphism if and only if  $\mathcal{C}$  satisfies additionally the congruence extension (or, equivalently, the transferability property).

If  $\mathcal{C}$  is (Barr-)exact, then one can replace the first “kernel pair” in (v) by “equivalence relation”.

PROOF. Let us first indicate some properties of the considered categories  $\mathcal{C}$ . The pair (Regular epis, Monos) is a factorization system on  $\mathcal{C}$ . Moreover, by Theorem 2.1 each monomorphism as well as each epimorphism is regular and for any diagram

$$\begin{array}{ccc}
 & & \downarrow e \\
 \alpha & \longrightarrow & \\
 \beta & \longrightarrow &
 \end{array} \tag{2.6}$$

with  $e$  being an epimorphism there exists a diagram

$$\begin{array}{ccc}
 \bar{\alpha} & \longrightarrow & \\
 \bar{e} \downarrow & \bar{\beta} & \downarrow e \\
 \alpha & \longrightarrow & \\
 \beta & \longrightarrow &
 \end{array} \tag{2.7}$$

such that  $\bar{e}$  is also an epimorphism and  $e\bar{\alpha} = \alpha\bar{e}$ ,  $e\bar{\beta} = \beta\bar{e}$ <sup>4</sup>.

The equivalences (ii)  $\Leftrightarrow$  (iii)  $\Leftrightarrow$  (iv) obviously follow from the presented properties. (i)  $\Leftrightarrow$  (ii) is the well-known fact proved, for instance, in [JT].

(iv)  $\Rightarrow$  (v): Let  $e$  be a coequalizer of  $(\alpha_1, \alpha_2)$ . Then  $e'$ , the pushout of  $e$  along  $f$ , is a

---

<sup>4</sup>We first take a pullback  $e_1$  of  $e$  along  $\alpha$  and then the pullback  $e_2$  of  $e$  along  $\beta e_1$ .  $e'$  is given by the composition  $e_2 e_1$ .

coequalizer of  $(f\alpha_1, f\alpha_2)$ . Consider the diagram

$$\begin{array}{ccccc}
 & & & & \\
 & & & & \\
 & & & & \\
 A & & & & \\
 & \searrow^{\beta_2} & & & \\
 & & R & \overset{f'}{\dashrightarrow} & R' \\
 & \searrow^{\beta_1} & \downarrow \alpha_1 & & \downarrow \alpha'_1 \\
 & & B & \xrightarrow{f} & E \\
 & & \downarrow e & & \downarrow e' \\
 & & C & \overset{g}{\dashrightarrow} & C'
 \end{array} \tag{2.8}$$

with any  $\beta_1, \beta_2, \gamma$  such that  $f\beta_1 = \alpha'_1\gamma$  and  $f\beta_2 = \alpha'_2\gamma$ . Then  $ge\beta_1 = e'f\beta_1 = e'f\beta_2 = ge\beta_2$ , whence  $e\beta_1 = e\beta_2$ , since  $g$  being the pushout of  $f$  along a (regular) epimorphism is a monomorphism. Since  $(\alpha_1, \alpha_2)$  is a kernel pair of  $e$ , we have a unique morphism  $\delta : A \rightarrow R$  such that  $\beta_1 = \alpha_1\delta$  and  $\beta_2 = \alpha_2\delta$ . Moreover,  $\alpha'_1f'\delta = f\alpha_1\delta = f\beta_1 = \alpha'_1\gamma$  and, similarly,  $\alpha'_2f'\delta = \alpha'_2\gamma$ , so that  $f'\delta = \gamma$ .

(v) $\Rightarrow$ (iv): Let  $g\alpha = g\beta$  and consider  $\bar{e}, \bar{\alpha}, \bar{\beta}$  from diagram (2.7). Clearly, one has  $e'f\bar{\alpha} = e'f\bar{\beta}$ , which gives a morphism  $\theta$  with  $\bar{\alpha} = \alpha_1\theta$  and  $\bar{\beta} = \alpha_2\theta$ . Therefore  $e\bar{\alpha} = e\bar{\beta}$ , from which it follows that  $\alpha = \beta$ . ■

For varieties of universal algebras the condition (v) of Proposition 2.2 clearly takes the form:

*For any congruence  $R$  on  $B$  and its closure  $R'$  in  $E$  one has*

$$R' \cap (B \times B) = R.$$

2.3. EXAMPLE. As is known, the varieties of  $M$ -sets (for a given monoid  $M$ ) [KMPT], groups [S], not necessarily associative rings [Di], Lie algebras (over a given field) [R], quasi-groups [YK1], commutative quasi-groups [YK], Steiner quasi-groups [KMPT], medial quasi-groups [JK], semilattices [HK], lattices [Y], [G], weakly associative lattices [FG], Boolean algebras [DY] and Heyting algebras [D] satisfy the strong amalgamation property. Moreover, the categories of  $M$ -sets [KMPT], semilattices [KMPT], [BL], Boolean algebras [Si] and Heyting algebras [D] possess the congruence extension property as well. In each case we give the reference (according to [KMPT]) where the corresponding property is determined for the first time.

### 3. Effective Codescent Morphisms of Groups

Proposition 2.2 gives rise to

3.1. THEOREM. *Let  $p : B \twoheadrightarrow E$  be a monomorphism of groups.  $p$  is a codescent morphism if and only if for any normal subgroup  $N$  of  $B$  and its normal closure  $N'$  in  $E$  one has*

$$N' \cap B = N.$$

*When  $B$  is a normal subgroup of  $E$ , this is equivalent to the requirement that any normal subgroup of  $B$  be normal in  $E$  as well.*

Before giving our main result, let us recall some well-known facts related to free products of groups with an amalgamated subgroup [Ku]. Let  $H$  be a group, and  $(H \xrightarrow{\varphi_i} G_i)_{i \in I}$  be a family of groups equipped with monomorphisms  $\varphi_i$ . Further, let  $G$  be a group containing (isomorphic copies of) all  $G_i$ , and let

$$G_i \cap G_j = H \tag{3.1}$$

for  $i \neq j$  (here we identify every  $h \in H$  with all  $\varphi_i(h)$ ). For any  $i \in I$  and any right coset of  $G_i$  by  $H$ , except for  $H$  itself, we choose a representative. We denote the set of all chosen representatives by  $A$ .  $G$  is a free product of  $(G_i)_{i \in I}$  with the amalgamated subgroup  $H$  if and only if every element of  $G$  can be uniquely written as a product

$$h a_1 a_2 \cdots a_n, \tag{3.2}$$

where  $n \geq 0$ ,  $h \in H$ , all  $a_j$  lie in  $A$  and no two  $a_j, a_{j+1}$  belong to the same  $G_i$ <sup>5</sup>. Form (3.2) is called canonical. It is easy to see how an element

$$a'_1 a'_2 \cdots a'_m \tag{3.3}$$

of  $G$  (taken in the uncancellable form) can be reduced to the canonical form. Indeed, if  $m = 1$  and  $a'_m \in H$ , then (3.3) is already the desired one. If again  $m = 1$ , but  $a'_m \in G_{i_m} \setminus H$ , then we consider the representation

$$a'_m = h \overline{a'_m} \tag{3.4}$$

with  $h \in H$  and  $\overline{a'_m} \in G_{i_m} \cap A$ ; (3.4) is the canonical form for (3.3). Let  $m > 1$  and  $a'_2 a'_3 \cdots a'_m$  be already reduced to the required form

$$a'_2 a'_3 \cdots a'_m = h' a_1 a_2 \cdots a_n$$

with  $a_j \in G_{i'_j} \cap A$ . If  $a'_1 \in H$ , then

$$(a'_1 h') a_1 a_2 \cdots a_n$$

---

<sup>5</sup>In fact, this criterion remains true even without requirement (3.1)—we only have to replace “set of representatives” by “system of representatives” and then to specify what kind of products (3.2) and the uniqueness is meant here.

is clearly the canonical form for (3.3). If  $a'_1 \in G_{i_1} \setminus H$ , then we consider the representation

$$a'_1 h' = h'' \overline{a'_1},$$

where  $h'' \in H$  and  $\overline{a'_1} \in G_{i_1} \cap A$ . If  $i_1 \neq i'_1$ , then

$$h'' \overline{a'_1} a_1 a_2 \cdots a_n$$

is the canonical form for (3.3). If  $i_1 = i'_1$  and  $\overline{a'_1} a_1 \in H$ , then

$$(h'' \overline{a'_1} a_1) a_2 \cdots a_n$$

is the required representation for (3.3). If  $i_1 = i'_1$  and  $\overline{a'_1} a_1 \notin H$ , then we have

$$\overline{a'_1} a_1 = h''' \overline{a'_1 a_1}$$

for some  $h''' \in H$  and  $\overline{a'_1 a_1} \in G_{i_1} \cap A$ ; the representation

$$h''' \overline{a'_1 a_1} a_2 \cdots a_n$$

is the desired form for (3.3).

Now it is clear that if  $a'_{j_1}, a'_{j_2}, \dots, a'_{j_k}$  are precisely those elements in (3.3) which do not lie in  $H$  and if  $i_{j_r} \neq i_{j_{r+1}}$  (!) for any  $1 \leq r \leq k-1$ , then in the canonical form of (3.3) we have exactly  $k$  factors (except, perhaps, for a coefficient from  $H$ ) and these factors belong to  $G_{i_{j_1}}, G_{i_{j_2}}, \dots, G_{i_{j_k}}$ , respectively. Indeed, in each step of the reduction we either pick out an  $H$ -coefficient from some  $a'_j$  or perform the relevant multiplication. Clearly, each  $a'_{j_r}$  is changed again by an element from  $G_{i_{j_r}} \setminus H$ , while no two  $a_{j_r}, a_{j_{r+1}}$  can “cancel” each other.

**3.2. PROPOSITION.** *For any monomorphism  $p : B \twoheadrightarrow E$  the action of  $\Phi_p$  on objects is surjective up to an isomorphism.*

**PROOF.** Let  $(C, \gamma, \xi)$  be codescent data with respect to  $p$ . The pushout in Fig. 1 is the concatenation of the following two pushouts:

$$\begin{array}{ccc}
 B & \xrightarrow{p} & E \\
 \downarrow & & \downarrow \\
 \gamma(B) & \xrightarrow{p'} & E/(\text{Ker } \gamma \cap B)' \\
 \downarrow i & & \downarrow i' \\
 C & \xrightarrow{\pi_1} & C \sqcup_{\gamma(B)} E/(\text{Ker } \gamma \cap B)'
 \end{array} \tag{3.5}$$

Here  $(\text{Ker } \gamma \cap B)'$  is the normal closure of  $(\text{Ker } \gamma \cap B)$  in  $E$ . From (1.2) we conclude that  $\pi_1$  and thus both  $p'$  and  $i'$  are monomorphisms.

From (1.1) we have

$$\xi(\gamma(E)) = \pi_2(E). \tag{3.6}$$

On the other hand, by (1.2)  $\xi$  is a split monomorphism. Therefore the homomorphism  $\gamma(E) \rightarrow \pi_2(E) \approx E/(\text{Ker } \gamma \cap B)'$  is an isomorphism and its inverse is the morphism induced by  $\gamma$ . This in particular implies that  $(\text{Ker } \gamma \cap B)' = \text{Ker } \gamma$  and thus diagram (3.5) takes the form

$$\begin{array}{ccc} B & \xrightarrow{p} & E \\ \downarrow & & \downarrow \\ \gamma(B) & \xrightarrow{p'} & \gamma(E) \\ \downarrow i & & \downarrow i' \\ C & \xrightarrow{\pi_1} & C \sqcup_{\gamma(B)} \gamma(E) \end{array}$$

If  $C = \gamma(E)$ , then  $(C, \gamma, \xi) \approx \Phi^p(B \rightarrow \gamma(B))$ .

Suppose now that  $C \neq \gamma(E)$ . Without loss of generality it can be assumed that  $p$  is not an isomorphism. Since we intend to work with the free product of the groups  $G_1 = C$  and  $G_2 = \gamma(E)$  (as well as with the free product of the groups  $G_1 = C$ ,  $G_2 = \gamma(E)$  and  $G_3$  being another copy of  $\gamma(E)$ ) with the amalgamated subgroup  $\gamma(B)$ , we choose a representative from each right coset (different from  $\gamma(B)$ ) of  $G_1$  and  $G_2$  (in  $G_3$  we choose the same representatives as in  $G_2$ ). Let  $c \in C \setminus \gamma(E)$  and let the canonical form of  $\xi(c)$  be written as

$$\xi(c) = \gamma(b) a_1 a_2 \cdots a_n. \tag{3.7}$$

We show that if  $a_i \in G_1$  for some  $i$ , then

$$\xi(a_i) \in G_1,$$

whence, by (1.2)

$$\xi(a_i) = a_i.$$

Let the canonical form of  $\xi(a_i)$  have the form

$$\xi(a_i) = \gamma(b') a'_1 a'_2 \cdots a'_m.$$

Clearly, by (1.2)  $m > 0$ . Suppose that at least one  $a'_j$  lies in  $G_2$ . From (1.3) we obtain

$$\begin{aligned} & \gamma(b) \cdots \textcircled{a_{i-1}} a_i \textcircled{a_{i+1}} \cdots \\ & = \gamma(b) \cdots \textcircled{a_{i-1}} \gamma(b') a'_1 a'_2 \cdots a'_m \textcircled{a_{i+1}} \cdots, \end{aligned} \tag{3.8}$$

where the elements in circles are considered as representatives of  $G_3$ . The left and right neighbors of any  $\gamma(b'')$  (if they exist) in the right part of (3.8) lie in different  $G_i$  ( $1 \leq i \leq 3$ ). Therefore, according to the observation preceding this proposition, the canonical form of

the right part of (3.8) necessarily contains a representative from  $G_2$ . On the other hand, the left part of (3.8) is already canonical and does not contain any representative from  $G_2$ , which is a contradiction.

Let  $C'$  be the smallest subgroup of  $C$  containing  $\gamma(B)$  and all elements of  $G_1$  which take part in representation (3.7) for some  $c \in C \setminus \gamma(E)$ . From (1.2) we obtain

$$c = \gamma(b) a'_1 a'_2 \cdots a'_n,$$

where each  $a'_i$  coincides either with  $a_i$  or with  $\gamma(a_i)$ . Thus  $C$  is generated by  $C'$  and  $\gamma(E)$ . Moreover, as we have just proved

$$\xi|_{C'} = \pi_1|_{C'}.$$

Therefore, after choosing a set of representatives from the right cosets of  $C'$  and  $\gamma(E)$  by  $\gamma(B)$ , we conclude that each element of  $C$  has precisely one canonical form. Thus  $C = C' \sqcup_{\gamma(B)} \gamma(E)$  and  $(C, \gamma, \xi) \approx \Phi^p(\gamma')$ , where  $\gamma' : B \rightarrow C'$  is the homomorphism induced by  $\gamma$ . ■

Proposition 3.2 immediately gives rise to

3.3. THEOREM. *In the category of groups every codescent morphism is effective.*

3.4. REMARK. It seems natural to ask what classes of effective codescent morphisms various comonadicity criteria determine in this case. In this connection, we only observe that for a monomorphism  $p : B \twoheadrightarrow E$ , the change-of-cobase functor  $p_*$  preserves (all) equalizers if and only if the intersection of any right and left cosets of  $E$  by  $B$  which are different from  $B$ , contains at most one element. The “if” part is easy to verify. For the “only if” part we consider the equalities  $tb = b's$  and  $tb_1 = b'_1s$  with  $t, s \in E \setminus B$ ,  $b, b', b_1, b'_1 \in B$  and choose a diagram

$$\begin{array}{ccccc}
 & & B & & \\
 & i_1 \nearrow & \downarrow i_2 & \nwarrow i_3 & \\
 C & \xrightarrow{\gamma} & D & \xrightarrow[\beta]{\alpha} & K
 \end{array}$$

with monomorphisms  $i_1, i_2, i_3$  such that the bottom part is an equalizer diagram and, moreover, there exist  $d, d' \in D \setminus B$  with  $b^{-1}\alpha(d) = b_1^{-1}\beta(d)$  and  $\alpha(d')b' = \beta(d')b'_1$ . It is easy to see that for the element  $x = d'td$  of  $D \sqcup_B E$  we have  $(\alpha \sqcup_B 1_E)(x) = (\beta \sqcup_B 1_E)(x)$ . Hence  $x = (\gamma \sqcup_B 1_E)(y)$  for some  $y \in C \sqcup_B E$ . If we choose representatives of the right cosets of  $C$  by  $B$ , then their images under  $\gamma$  can be taken as representatives of (some) right cosets of  $D$ . The canonical form of  $y$  necessarily ends in an element  $c$  from  $C$ . We have  $\gamma(c) = b'''d$  for some  $b''' \in B$  and therefore  $\alpha(d) = \beta(d)$  and  $b = b_1, b' = b'_1$ .

In particular, when  $B$  is normal in  $E$ ,  $p_*$  preserves equalizers if and only if  $B$  is trivial.

THEORY AND APPLICATIONS OF CATEGORIES (ISSN 1201-561X) will disseminate articles that significantly advance the study of categorical algebra or methods, or that make significant new contributions to mathematical science using categorical methods. The scope of the journal includes: all areas of pure category theory, including higher dimensional categories; applications of category theory to algebra, geometry and topology and other areas of mathematics; applications of category theory to computer science, physics and other mathematical sciences; contributions to scientific knowledge that make use of categorical methods.

Articles appearing in the journal have been carefully and critically refereed under the responsibility of members of the Editorial Board. Only papers judged to be both significant and excellent are accepted for publication.

The method of distribution of the journal is via the Internet tools `WWW/ftp`. The journal is archived electronically and in printed paper format.

**SUBSCRIPTION INFORMATION.** Individual subscribers receive (by e-mail) abstracts of articles as they are published. Full text of published articles is available in .dvi, Postscript and PDF. Details will be e-mailed to new subscribers. To subscribe, send e-mail to `tac@mta.ca` including a full name and postal address. For institutional subscription, send enquiries to the Managing Editor, Robert Rosebrugh, `rosebrugh@mta.ca`.

**INFORMATION FOR AUTHORS.** The typesetting language of the journal is  $\text{\TeX}$ , and  $\text{\LaTeX}$  is the preferred flavour.  $\text{\TeX}$  source of articles for publication should be submitted by e-mail directly to an appropriate Editor. They are listed below. Please obtain detailed information on submission format and style files from the journal's WWW server at <http://www.tac.mta.ca/tac/>. You may also write to `tac@mta.ca` to receive details by e-mail.

#### EDITORIAL BOARD.
