

Intersections of automorphism fixed subgroups in the free group of rank three

A. Martino

Abstract We show that in the free group of rank 3, given an arbitrary number of automorphisms, the intersection of their fixed subgroups is equal to the fixed subgroup of some other single automorphism.

AMS Classification 20E05; 20F28

Keywords Free group, Automorphism, Fixed subgroup

1 Introduction

Let F_n be a free group of rank n .

Definition 1.1 The fixed subgroup of an automorphism α of F_n , denoted $\text{Fix } \alpha$, is the subgroup of elements in F_n fixed by α :

$$\text{Fix } \alpha = \{x \in F_n : x = \alpha(x)\}$$

Following the terminology introduced in [14], a subgroup H of F_n is called 1-auto-fixed when there exists an automorphism α of F_n such that $H = \text{Fix } \alpha$. An auto-fixed subgroup of F_n is an arbitrary intersection of 1-auto-fixed subgroups. If $S \leq \text{Aut}(F_n)$ then

$$\text{Fix } S = \{x \in F_n : x = \alpha(x) \text{ for all } \alpha \in S\} = \bigcap_{\alpha \in S} \text{Fix } \alpha$$

is an auto-fixed subgroup. Moreover if S is a subgroup of $\text{Aut}(F_n)$ generated by S_0 then $\text{Fix } S = \text{Fix } S_0$.

The celebrated result of Bestvina-Handel [4] showed that a 1-auto-fixed subgroup of F_n has rank at most n . This was extended by Dicks-Ventura [6]. The following Theorem is a special case of the main result in [6].

Theorem 1.2 *Let H be a 1-auto- xed subgroup of F_n and K a nitely generated subgroup of F_n . Then $\text{rank}(H \setminus K) = \text{rank}(K)$. In particular, putting $K = F_n$ we get that $\text{rank}(H) = n$.*

In [14] it was conjectured that the families of auto- xed and 1-auto- xed subgroups of F_n coincide. The authors proved some partial results in this direction but, in general, the conjecture was only known to be true for $n = 2$.

In this paper we show, in Corollary 5.3, that any auto- xed subgroup of F_3 is a 1-auto- xed subgroup of F_3 . The work in this paper also shows, in Corollary 3.17, that auto- xed subgroups are 1-auto- xed for an important class of automorphisms called Unipotent Polynomially Growing (UPG) automorphisms, introduced in [3].

The author gratefully acknowledges the postdoctoral grant SB2001-0128 funded by the Spanish government, and thanks the CRM for its hospitality during the period of this research.

2 Preliminaries

It was shown in [4] that any outer automorphism of a nitely generated free group has either polynomial or exponential growth. We review those notions here.

The growth rate of an automorphism, ϕ , of a free group F is the function of k given by the quantity

$$\sup_{w \in F} \frac{|w|_k}{|\phi^k(w)|_k}$$

where $|w|_k$ denotes word length, with respect to a given basis. An automorphism has polynomial growth if its growth function is bounded above by a polynomial function of k and exponential growth if it is bounded below by an exponential function of k . Note that the growth function is always bounded above by an exponential function of k . Clearly, the division into polynomial and exponential growth automorphisms is independent from the generating set in question.

One could also replace word length with *cyclic* word length - the word length of a shortest conjugate - and the notions of polynomial growth and exponential growth are preserved. Thus the notion of growth rate applies to outer automorphisms, via cyclic lengths. An outer automorphism, ϕ , has polynomial growth if and only if any automorphism $\psi \in \text{Out}(F)$ has polynomial growth. (Having said

that, the degrees of the polynomials in question may differ by at most one.) Similarly \mathbb{Z}^n has exponential growth if and only if \mathbb{Z}^2 has exponential growth. Of particular interest here is the following class, defined in [3], Definitions 3.1 and 3.10.

Definition 2.1 An outer automorphism, ϕ , of the free group of rank n , F_n is said to be Unipotent Polynomially Growing (UPG) if it is of polynomial growth and its induced action on $F_n/F_n^l = \mathbb{Z}^n$, also denoted by ϕ , satisfies one of the following two equivalent conditions.

- (i) \mathbb{Z}^n has a basis with respect to which ϕ is upper triangular with 1's on the diagonal,
- (ii) $(Id - \phi)^k = 0$ for some $k > 0$.

Since we are interested in actual automorphisms and subgroups, we extend the above notion to these.

Definition 2.2 Let $\phi \in Out(F_n)$ and let $\Gamma \leq \phi$. Then Γ is called UPG if and only if ϕ is UPG. A subgroup of $Out(F_n)$ or $Aut(F_n)$ is called UPG if every element of the subgroup is UPG.

A marked graph is a graph, G , in the sense of Serre, with a homotopy equivalence f from R_n , the rose with n petals (n edges and a single vertex, v) to G . We identify the free group of rank n , F_n , with the fundamental group of R_n . The marking thus gives a specified way to identify the fundamental group of G with F_n .

Suppose that ϕ sends v to the vertex v of G and that $f : G \rightarrow R_n$ is a homotopy equivalence which sends vertices to vertices and edges to edge paths, such that $f(v) = u$. If ρ is any path from u to v , then the isomorphism $\rho_* : \pi_1(G; u) \rightarrow \pi_1(G; v)$ is defined by $\rho_*([\gamma]) = [\rho \gamma]$. The map $\rho_* \phi$ is then an automorphism of $\pi_1(G; v)$ and the automorphism, $\phi_{f; \rho}$ is then defined so as to make the following diagram commute.

$$\begin{array}{ccc}
 F_n & \longrightarrow & \pi_1(G; v) \\
 \downarrow \phi_{f; \rho} & & \downarrow \phi \\
 & & \pi_1(G; u) \\
 & & \downarrow \rho_* \\
 F_n & \longrightarrow & \pi_1(G; v)
 \end{array}$$

As the path ρ varies amongst all paths between u and v , the collection of automorphisms $\gamma; \rho$ form an outer automorphism $\gamma; f$.

As in [3], we shall mostly be interested in the case where G is iterated, which is to say that there are subgraphs $\gamma; = G_0 \subset G_1 \subset \dots \subset G_k = G$, where the G_i (not necessarily connected) of G . Moreover, each G_i is obtained from G_{i-1} by the addition of a single edge E_i . A map, $f : G \rightarrow G$, is upper triangular with respect to the iteration, or simply upper triangular, if for each i , $f(E_i) = E_i u_i$, where u_i is a loop in G_{i-1} . Note that this means each edge, and hence the entire graph G , has a preferred orientation. It is easy to check that any upper triangular map is a homotopy equivalence on G .

We shall sometimes say that a iterated graph G consists of the edges $E_1; \dots; E_m$. By this we mean that we have taken one oriented edge from each edge pair of G , that the iteration of subgraphs is given by setting G_i to be the subgraph generated by $E_1; \dots; E_i$ and that the given edges are the preferred orientation for G .

We note that this differs from [3] in that we have trivial prexes, which is to say that the image of E_i starts with E_i rather than another loop in G_{i-1} . The more general situation may be reduced to ours by a sequence of subdivisions.

For a iterated graph, G , one can define Q to be the set of upper triangular homotopy equivalences, as above. This turns out to be a group, under composition, which lifts via the marking to a UPG subgroup of $Out(F_n)$. Conversely, a subgroup of $Out(F_n)$ is said to be iterated if it is the lift of a subgroup of such a Q for some G . We rely crucially on the following result from [3].

Theorem 2.3 Every finitely generated UPG subgroup of $Out(F_n)$ is iterated.

We shall also need some further results.

Proposition 2.4 ([3], Proposition 4.16) Let γ be a UPG automorphism of F and $H \leq F$ a primitive subgroup of F . (That is, $x^k \in H$ implies $x \in H$, for all group elements x and all positive integers k .) If $\gamma^m(H) = H$ then, in fact, $\gamma(H) = H$ and moreover, γ restricts to a UPG automorphism of H .

The following shows that periodic points are fixed by UPG automorphisms.

Proposition 2.5 Let $\gamma \in Aut(F_n)$ be a UPG automorphism and suppose that $\gamma^k(x) = x$ for some $x \in F_n$. Then $\gamma(x) = x$.

Proof Without loss we may assume that x is not a proper power and thus $H = \langle x \rangle$ is a primitive subgroup. By Proposition 2.4, $\gamma(H) = H$ and γ restricts to a UPG outer automorphism of H . This implies that $\gamma(x) = x$. □

3 Upper triangular maps

Throughout this section, G will be a filtered graph with upper triangular maps f and g . Note that f and g induce UPG outer automorphisms on the fundamental group of G . The edges (and a preferred orientation) of G will be E_1, \dots, E_m so that the subgraph G_r containing edges E_1, \dots, E_r is invariant under both f and g . Recall that \overline{E} denotes the edge with reversed orientation to E and for a path γ , $\overline{\gamma}$ denotes the inverse path. By definition we have that, $f(E_i) = E_i u_i$, $g(E_i) = E_i v_i$ where u_i, v_i are loops in G_{i-1} . Paths in G will always be edge paths, that is sequences of oriented edges, except for the *trivial* paths which will consist of a single vertex. Note that all vertices of G are fixed by both f and g .

We write $\gamma = \delta$ if the paths γ and δ are the same sequence. We will write $\gamma \sim \delta$ to denote homotopy equivalence of the paths with respect to the endpoints, and write $[\gamma]$ for the homotopy class of the path γ .

An edge path is reduced if the sequence of edges contain no adjacent inverse edges and cyclically reduced if additionally, the first and last edges are not inverse edges. In each homotopy class of paths, $[\gamma]$ there is a unique reduced path which we denote $\gamma_{\#}$. Write $j(\gamma)$ for the number of edges in the path $\gamma_{\#}$.

Following [2], section 4.1, the decomposition of a path $\gamma = \gamma_1 \gamma_2 \dots \gamma_t$ is said to be a splitting for f if for every positive integer k , the reduced path $f^k(\gamma)_{\#}$ is obtained by concatenating the reduced paths $f^k(\gamma_i)_{\#}$. Namely, we have that $f^k(\gamma)_{\#} = f^k(\gamma_1)_{\#} \dots f^k(\gamma_t)_{\#}$. Now, given such a splitting, if we set $\gamma^0 = \gamma_1 \gamma_{i+1}$ then we get another splitting of γ , $\gamma = \gamma_1 \dots \gamma_{i-1} \gamma^0 \gamma_{i+2} \dots \gamma_t$ which we call a coarsening of the splitting.

Each path γ has a height, denoted $ht(\gamma)$, which is an integer r such that E_r or $\overline{E_r}$ occurs in γ but no E_s or $\overline{E_s}$ occurs in γ for $s > r$. A *basic path of height r* is a path of the form E_r , $\overline{E_r}$ or $E_r \overline{E_r}$ where γ is a path of height less than r . The following lemma is proved in [2] for a single map.

Lemma 3.1 ([2], Lemma 4.1.4) *Let γ be a reduced path of height r . Then γ has a splitting for f into paths which are either basic paths of height r or paths of height less than r .*

Note that any path γ of height r has a unique decomposition into a minimal number of paths which are either basic of height r or of height less than r . Moreover, this unique decomposition is always a coarsening of the decomposition given by Lemma 3.1. Hence we get the following,

Lemma 3.2 *Let γ be a reduced path of height r . Then γ has a splitting simultaneously for f and g into paths which are either basic paths of height r or paths of height less than r .*

An easy calculation provides the following.

Lemma 3.3 *Let γ be a basic path of height r . If γ begins with E_r then so does $f(\gamma)_\#$ and if γ ends with $\overline{E_r}$ then so does $f(\gamma)_\#$.*

Proof The Lemma is clear if $\gamma = E_r$ or $\overline{E_r}$. Thus there is only something to show if $\gamma = E_r \overline{E_r}$. In this case, γ is a loop and hence neither $f(\gamma)$ nor $u_r f(\gamma) \overline{u_r}$ can be homotopic to the trivial path and hence $f(\gamma)_\# = E_r (u_r f(\gamma) \overline{u_r})_\# \overline{E_r}$. □

Hence we get the following immediate consequence to Lemmas 3.2 and 3.3.

Corollary 3.4 *Let γ be a path in G which is not homotopic to a trivial path. Then $f(\gamma)$ and $g(\gamma)$ are not homotopic to trivial paths.*

Definition 3.5 Let γ be a path of height r which is cyclically reduced. If either the first edge of γ is E_r or the last edge is $\overline{E_r}$ then we call γ G -reduced.

Lemma 3.6 *Let γ be a G -reduced path. Then $f(\gamma)_\#$ is also G -reduced.*

Proof Suppose γ begins with E_r . We will show that $f(\gamma)_\#$ and $g(\gamma)_\#$ are cyclically reduced and begin with E_r .

First, by coarsening the splitting of Lemma 3.2, there is a splitting of $\gamma = \gamma_1 \gamma_2 \gamma_3$ where γ_1 is a basic path of height r and γ_3 is either a basic path of height r or is a path of height less than r . Then γ_1 is either equal to E_r or $E_r \overline{E_r}$ for some path γ' of height less than r . Hence, by Lemma 3.3, $f(\gamma_1)_\#$ and hence $f(\gamma)_\#$ begins with E_r .

So it remains to show that $f(\gamma)_\#$ is cyclically reduced, which is to say that it does not end with $\overline{E_r}$. If the path γ_3 is of height less than r then $f(\gamma_3)$ is not homotopic to a trivial path, by Corollary 3.4, and we are done. Otherwise, γ_3 is a basic path of height r which cannot end in $\overline{E_r}$ and hence is of the form $E_r \gamma'$ for some path γ' of height less than r . Clearly, $f(\gamma_3)_\#$ is not a trivial path and cannot end in $\overline{E_r}$. This proves the Lemma when γ begins with E_r and the same proof works for the case when γ ends in $\overline{E_r}$ by just repeating the argument for $\overline{\gamma}$. □

Lemma 3.7 Let α, β be homotopically non-trivial loops of the same height based at the same vertex such that $\langle \alpha, \beta \rangle$ is a free group of rank 2 and α is G -reduced. Then there exist positive integers p, q such that $(\alpha^p \beta^q)_\#$ is G -reduced.

Proof Let $p > j(\alpha)$. Then, as α is G -reduced, $\alpha^p = p(\alpha)$ $p > j(\alpha)$. Hence, the first letter of $(\alpha^p)_\#$ is the same as the first letter of α . We note that this implies,

$$\alpha^{p+1} = \alpha^p \alpha$$

Let $q > j(\alpha^{p+1}) > j(\alpha^p)$ and consider $(\alpha^p \beta^q)_\#$. The only way this can fail to be G -reduced is if $(\alpha^p)_\#$ is a terminal subpath of β^{-q} . Thus $\alpha^p = \beta^{-q_1}$ (reduced as written) and

$$\alpha^p = \beta^{-q_1} \tag{1}$$

for some positive integer, q_1 . Note that we choose q_1 maximally so that $\beta^{-q_1} \notin \langle \alpha \rangle$.

We repeat this argument for $\alpha^{p+1} \beta^q$. Either this is G -reduced, and we are done, or $\alpha^{p+1} \beta^q = \beta^{-q_2}$ reduced as written and

$$\alpha^{p+1} \beta^q = \beta^{-q_2} \tag{2}$$

for some positive integer q_2 . As before, $\beta^{-q_2} \notin \langle \alpha \rangle$.

The difference in the lengths of the left hand sides of equations 1 and 2 is, as noted above, equal to $j(\alpha)$. Hence the right hand sides must also differ in length by this amount. Thus,

$$\begin{aligned} j(\alpha^p) &= j(\beta^{-q_1}) - j(\beta^{-q_2}) \\ &= (j(\beta^{-q_1}) + j(\beta^{q_2})) - (j(\beta^{-q_1}) + j(\beta^{q_1})) \text{, since } \beta \text{ is cyclically reduced} \\ &= (q_2 - q_1)j(\alpha) \end{aligned}$$

However, $\beta^{-q_1}, \beta^{-q_2}$ are both initial subpaths of α^p , neither of which is equal to α^p and so the quantity $j(\beta^{-q_1}) - j(\beta^{-q_2})$ must have modulus strictly less than $j(\alpha)$. Hence $q_1 = q_2$ and $q_2 = q_1 + 1$. This implies that

$$\begin{aligned} & \alpha^p = \beta^{-q_1} \text{ by inspection} \\ & \alpha^{p+1} \beta^q = \beta^{-q_1-1} \text{ by equations 1 and 2} \\ & \alpha = \beta^{-1} \end{aligned}$$

This implies that $\beta^{-1} \notin \langle \alpha \rangle$ is conjugate to its inverse in a free group. As this cannot happen we get a contradiction and thus prove the result. \square

Proposition 3.8 Let α be a G -reduced loop which is fixed up to free homotopy by f . Then $f(\alpha) = \alpha$.

Proof Now γ is a G -reduced loop and $f(\gamma)$ is both G -reduced by Lemma 3.6 and freely homotopic to γ by hypothesis. However, there are only finitely many G -reduced paths freely homotopic to γ (they are a subset of the cyclic permutations of γ). Hence, $f^k(\gamma)_\# = \gamma$ for some k . The loop γ has a basepoint at some vertex which we denote by v . Now f induces a UPG automorphism at $\pi_1(G; v)$ whose k^{th} power fixes $[\gamma]$. By Proposition 2.5 we get that $f(\gamma) = \gamma$. \square

The following result is perhaps the key result of the paper. It is an analogue of the Fixed Point Lemma (Corollary 2.2 of [4]) for a pair of maps. It would be of general interest to see if the following Theorem were true in general, rather than for the UPG case which we restrict ourselves to.

Theorem 3.9 *Let f, g be upper triangular maps on G . Suppose that γ_1, γ_2 are loops based at a vertex v in G , which generate a free group of rank 2 in $\pi_1(G; v)$. Suppose that α_i, β_i are paths such that $f(\alpha_i) = \alpha_i^{-1}$ and $g(\beta_i) = \beta_i^{-1}$ for $i = 1, 2$. Then there exists a path γ such that $f(\gamma) = \gamma^{-1}$ and $g(\gamma) = \gamma^{-1}$. Moreover, $ht(\gamma) = \max\{ht(\gamma_1), ht(\gamma_2)\}$.*

Proof Consider the set of loops corresponding to the elements of $\mathcal{H}[\gamma_1][\gamma_2]i$. To each such loop, γ , we can find a G -reduced loop, γ_0 , freely homotopic to it. By Proposition 3.8, γ_0 will be fixed by both f and g up to based homotopy. Amongst all the possible choices, we choose an γ_0 which is of minimal height and which is not a proper power. Note that there exists a path, which we call α_0 such that $\gamma_0 = \alpha_0 \overline{\gamma_0}$. Moreover, $ht(\gamma_0) = ht(\gamma) = \max\{ht(\gamma_1), ht(\gamma_2)\}$.

Let $\alpha_0 = \overline{f(\alpha_0)} \alpha_0$ and $\beta_0 = \overline{g(\beta_0)} \beta_0$ and note that since γ_0 is fixed up to based homotopy, α_0, β_0 are loops. Hence,

$$\begin{aligned} \alpha_0 \overline{\alpha_0} &= \overline{f(\alpha_0)} \alpha_0 \overline{\alpha_0} f(\alpha_0); \text{ by definition of } \alpha_0 \\ &= \overline{f(\alpha_0)} \alpha_0^{-1} f(\alpha_0); \text{ by definition of } \alpha_0 \\ &= \overline{f(\alpha_0)} f(\alpha_0) f(\alpha_0); \text{ by hypothesis, since } [\alpha_0] \geq \mathcal{H}[\gamma_1][\gamma_2]i \\ &= \overline{f(\alpha_0)} f(\alpha_0 \overline{\alpha_0}) f(\alpha_0); \text{ by definition of } \alpha_0 \\ &= \overline{f(\alpha_0)} f(\alpha_0) \overline{\alpha_0} f(\alpha_0); \text{ since } f(\alpha_0) = \alpha_0^{-1} \end{aligned}$$

As α_0 is not a proper power, we must have that $[\alpha_0] \geq \mathcal{H}[\gamma_1]i$. The same calculation for g shows that $[\beta_0] \geq \mathcal{H}[\gamma_2]i$, also.

Choose another loop γ^0 representing an element of $\mathcal{H}[\gamma_1][\gamma_2]i$ so that $[\gamma^0]$ and $[\alpha_0]$ generate a free group of rank 2. Now let $\gamma = (\overline{\alpha_0} \gamma^0)_\#$.

It is straightforward to verify that $f(\gamma) = \gamma^{-1}$ and $g(\gamma) = \gamma^{-1}$. Now, by minimality of $ht(\gamma)$, $ht(\gamma) = ht(\gamma) = ht(\alpha_0) = ht(\gamma^0)$. The proof now separates into two cases.

Case 1 $r = ht(\gamma) > ht(\gamma_0)$

By Lemma 3.2, γ has a splitting into paths which are basic paths of height r or paths of height less than r . Let $\gamma = \gamma_1 \cdots \gamma_k$ be such a splitting. Note that if $k = 1$, then γ is a basic path of height r and γ_0 either begins with E_r or ends with $\overline{E_r}$ (or both). But then, by Lemma 3.3, $f(\gamma)$ will also either begin with E_r or end with $\overline{E_r}$ and the fact that $f(\gamma) \cdot \gamma_0^{-1}$ would mean that γ_0 is homotopic to a trivial path and hence that $f(\gamma_0) \cdot \gamma_0^{-1}$. Similarly, $g(\gamma_0) \cdot \gamma_0^{-1}$ and we would be finished. Hence, we may assume that $k \geq 2$.

After coarsening the splitting, we may assume that if γ_1 is a path of height less than r , then γ_2 is a basic path of height r starting with E_r . Similarly, if γ_k is a path of height less than r , then γ_{k-1} is a basic path of height r ending in $\overline{E_r}$. Thus,

$$f(\gamma)_{\#} = f(\gamma_1)_{\#} \cdots f(\gamma_k)_{\#} \cdot \gamma_0^{-1}$$

However, the fact that $ht(\gamma_0) < r$ implies that

$$(\gamma_0^{-1})_{\#} = (\gamma_0^{-1})_{\#} \gamma_2 \cdots \gamma_{k-1} (\gamma_k^{-1})_{\#}$$

(Our coarsening of the splitting ensures that γ_0 cannot cause any cancellation with γ_2 or γ_{k-1}).

Thus we conclude that $f(\gamma_k) \cdot \gamma_k^{-1}$. Hence,

$$f(\gamma_k^{-1}) \cdot \gamma_k^{-1} = \gamma_k^{-1} f(\gamma_k) \cdot \gamma_k^{-1} \\ \cdot \gamma_k^{-1}; \text{ by definition of } \gamma_0$$

Similarly, $g(\gamma_{k-1}) \cdot \gamma_{k-1}^{-1}$ and we would be done in this case.

Case 2 $ht(\gamma) = ht(\gamma_0)$

By Lemma 3.7 it is possible to find positive integers p, q , such that $\gamma^p \gamma^q$ is G -reduced. Then, by Proposition 3.8, $\gamma^p \gamma^q$ will be fixed (up to homotopy rel endpoints) by both f and g . However, by construction

$$f(\gamma^p \gamma^q) \cdot \gamma_0^{-p-q} \\ g(\gamma^p \gamma^q) \cdot \gamma_0^{-p-q}$$

Thus,

$$[\gamma_0] : [\gamma_0] \geq h[\gamma] \setminus h[\gamma^p \gamma^q]$$

By definition of γ_0 this last intersection is trivial, and hence $\gamma_0 \cdot \gamma_0^{-1} = 1$, $f(\gamma_0) \cdot \gamma_0^{-1} = 1$, $g(\gamma_0) \cdot \gamma_0^{-1} = 1$. In other words, the theorem is proved with the requisite $\gamma_0 = 1$. \square

The next step is to analyse the fixed paths in G .

Definition 3.10 A path γ in G is said to be a common Nielsen Path (NP) for f and g if it is fixed up to homotopy by both f and g . γ is said to be a common Indivisible Nielsen Path (INP) for f and g if it is a common NP and no subpath of γ is an NP.

The following is immediate from Lemma 3.2.

Lemma 3.11 Let γ be a common INP of height r . Then γ is a basic path of height r .

Proposition 3.12 Let f^0, g^0 be upper triangular maps on a filtered graph G^0 . Then there is another filtered graph $G = fE_1; \dots; E_m g$, with upper triangular maps f, g and a homotopy equivalence $\eta : G^0 \rightarrow G$ such that the following diagrams commute up to free homotopy.

$$\begin{array}{ccc} G^0 & \longrightarrow & G \\ \downarrow f^0 & & \downarrow f \\ G^0 & \longrightarrow & G \end{array} \quad \begin{array}{ccc} G^0 & \longrightarrow & G \\ \downarrow g^0 & & \downarrow g \\ G^0 & \longrightarrow & G \end{array}$$

Moreover, the maps f and g satisfy the following properties:

(i) If there is a common Nielsen path of height r then there exist integers r_f, r_g (possibly zero) and a common Nielsen path γ_r of height at most $r - 1$ such that

$$f(E_r) = E_r \gamma_r^{r_f}; g(E_r) = E_r \gamma_r^{r_g};$$

(ii) Up to taking powers, there is a unique common INP of height r . It is $E_r \gamma_r^{r_f}$ unless $r_f = r_g = 0$ in which case it is E_r .

Proof We will find G from G^0 by performing a sequence of sliding moves (as in [2], section 5.4). Now G^0 has (oriented) edges $E_1^0; \dots; E_m^0$ so that the subgraph generated by $E_1^0; \dots; E_r^0$ is the r^{th} term in the filtration of G , and $f(E_r^0) = E_r^0 u_r^0, g(E_r^0) = E_r^0 v_r^0$. Given any path γ of height less than r which starts at the terminal vertex of E_r^0 we can slide E_r^0 along γ . Namely, we define a new graph G , with the same vertex set as G^0 and where all the edges E_i^0 are also edges of G (with the same incidence relations) except for E_r^0 . We have an edge, called E_r , of G which starts at the same vertex as E_r^0 and ends at the same vertex as γ . Informally, we will have that $E_r = E_r^0 \gamma$. The filtration for G will be the same as that for G^0 , just replacing E_r^0 with E_r .

Define the homotopy equivalence, η to be identical on the vertices, and send each E_i^0 to E_i^0 for $i \neq r$. Then let $\eta(E_r^0) = E_r^-$. (Note that γ is of height less than r , so can be considered as a path in both G and G^0 .)

Now, let f agree with f^∂ on $G^\partial - fE_r g$. If the f^∂ image of an edge includes some E_r^∂ we replace each occurrence with E_r^- and then reduce the path. This defines f on all edges except E_r where we let $f(E_r) = E_r(\bar{u}_r^\partial f^\partial(\))_\#$. Again, note that both \bar{u}_r^∂ and $f^\partial(\)$ are paths of height less than r . (In fact $f^\partial(\)$ is the same path as $f(\)$). By construction, $f \sim f^\partial$. Observe that this is more than an equivalence up to free homotopy, it is also a homotopy equivalence relative to the vertex sets of G and G^∂ . The inverse map to f is one which sends E_i^∂ to E_i^∂ for $i \neq r$ and sends E_r to E_r^∂ . Similarly, we can define g and note that $g(E_r) = E_r(\bar{v}_r^\partial g^\partial(\))_\#$.

Now the fact that f is a homotopy equivalence relative to the vertex sets means that if $f^\partial(E_i^\partial) = E_i^\partial u_i^\partial$ for $i \neq r$ where u_i^∂ is a NP then \bar{u}_i^∂ is also a NP path for f and $f(E_i^\partial) = E_i^\partial(\bar{u}_i^\partial)_\#$. Also it is clear that both f and its homotopy inverse preserve the height of paths and send basic paths to basic paths of the same type. The strategy is to perform sliding moves so as to make properties (i) and (ii) hold for as many edges as possible. The above comments show that if we slide E_r^∂ along some path, we do not disturb properties (i) and (ii) for other edges.

Thus it is sufficient to show that we may perform sliding homotopies for the edge E_r^∂ so that properties (i) and (ii) hold for the resulting maps f and g with respect to E_r .

Suppose there is a common Nielsen path for f^∂ and g^∂ of height r . Hence there must be a common indivisible Nielsen path of height r which, by Lemma 3.11 and up to orientation, must be of the form E_r^∂ or $E_r^\partial \bar{E}_r^\partial$ where \bar{E}_r^∂ is a path of height at most $r - 1$. In the former case we slide E_r^∂ along \bar{E}_r^∂ and then both f and g fix E_r , to satisfy (i) and (ii).

So we shall assume that there is no common INP of the form E_r^∂ . Thus we are in the latter case, and there is a common INP of the form $E_r^\partial \bar{E}_r^\partial$, where \bar{E}_r^∂ is not a proper power.

Now we can find a path, \bar{u}_r , of height less than r such that $(\bar{u}_r)_\#$ is G^∂ reduced. Let $\bar{v}_r = (\bar{u}_r)_\#$. Then by, Proposition 3.8, \bar{v}_r is fixed by f^∂ and g^∂ . Moreover,

$$\begin{aligned} \bar{v}_r &\sim f^\partial(\bar{u}_r); \text{ as } \bar{u}_r \text{ is fixed} \\ &\sim f^\partial(\bar{u}_r) \\ &\sim f^\partial(\bar{u}_r) f^\partial(\bar{u}_r) f^\partial(\bar{u}_r) \\ &\sim f^\partial(\bar{u}_r) \bar{u}_r^\partial f^\partial(\bar{u}_r); \text{ as } E_r^\partial \bar{E}_r^\partial \text{ is fixed} \\ &\sim f^\partial(\bar{u}_r) \bar{u}_r^\partial \bar{v}_r^\partial f^\partial(\bar{u}_r) \end{aligned}$$

Hence, $(\bar{u}_r^\partial f^\partial(\bar{u}_r))_\# = \bar{v}_r^{r_f}$ for some integer, r_f . Hence, if we slide E_r^∂ along \bar{u}_r , we get that $f(E_r) = E_r \bar{v}_r^{r_f}$, where \bar{v}_r is a NP of both f and g of height less than r . Similarly, $g(E_r) = E_r \bar{v}_r^{r_g}$ for some integer, r_g .

Now if for our new maps, f, g , the NP $E_r \overline{E_r}$ is the only NP which is a basic path of height r , then it must be an INP and we would be done. By assumption, there is no common NP of the form E_r (strictly speaking, we have assumed there is no such in G^j , but the existence of such a common NP for f and g in G implies that there is also one in G^j for f^j and g^j).

So let us assume that there is a common NP of the form $E_r \overline{E_r}$ for f and g , where $\overline{E_r}$ is not a power of E_r , and arrive at a contradiction.

Then, $[\gamma] ; [\eta]$ are loops based at the same vertex and must generate a free group of rank 2. Moreover, $f(\gamma) = \overline{r^f} \gamma^f$ and $g(\eta) = \overline{r^g} \eta^g$ and recall that E_r is a NP for both f and g . Hence, by Proposition 3.9, there exists a path γ_0 of height less than r such that $f(\gamma_0) = \gamma_0^f$ and $g(\eta_0) = \eta_0^g$. This means that $E_r \gamma_0$ is a common NP for f and g . This contradiction completes the proof. \square

Proposition 3.13 *Let $f;g$ be Upper triangular maps satisfying the conclusion of Proposition 3.12. If there is no common INP of height r then no common Nielsen path can cross E_r .*

Proof We argue by contradiction. Let γ be a common Nielsen path of height $k < r$ which crosses E_r and choose k to be the smallest integer with this property. The point is that E_r is an edge in γ but, a priori, we do not know if there is an INP of height r as a subpath of γ .

We decompose γ into common INP's. If E_k is a common INP itself then this decomposition is into paths each of which is equal to E_k or is a common INP of height at most $k - 1$. Thus either $r = k$ or E_r is an edge in a common INP of height at most $k - 1$. The former contradicts the hypotheses and the latter the minimality of k .

If E_k is not a common INP then by Proposition 3.12, every common INP of height k is equal to $E_k \overline{E_k^m}$ for some integer m , where E_k is a common INP of height at most $k - 1$. Thus γ can be written as a product of common INP's each of which is equal to (a power of) $E_k \overline{E_k}$ or is an INP of height at most $k - 1$. Thus either $E_r = E_k$, contradicting the hypotheses or E_r is an edge in a Nielsen path of height at most $k - 1$, contradicting the minimality of k . \square

Theorem 3.14 *Let $h, i \in 2 \text{Aut}(F_n)$ such that $h; i$ is a UPG subgroup and $\text{Fix } h \setminus \text{Fix } i$ is a free group of rank at least two which is contained in no proper free factor of F_n . Then there exists a iterated graph $G = fE_1; \dots; E_m g$, upper*

triangular maps $f; g: G \rightarrow G$ and an isomorphism $\alpha: F_n \rightarrow \pi_1(G; \nu)$ such that the following diagrams commute:

$$\begin{array}{ccc} F_n & \longrightarrow & \pi_1(G; \nu) \\ \downarrow & & \downarrow f \\ F_n & \longrightarrow & \pi_1(G; \nu) \end{array} \quad \begin{array}{ccc} F_n & \longrightarrow & \pi_1(G; \nu) \\ \downarrow & & \downarrow g \\ F_n & \longrightarrow & \pi_1(G; \nu) \end{array}$$

Moreover, $f(E_r) = E_{r-r_f} r_f$ and $g(E_r) = E_{r-r_g} r_g$ where E_r is a common NP of height at most $r-1$ and r_f, r_g are integers. The only common INP of height r is (a power of) $E_{r-r} \overline{E_r}$, unless $r_f = r_g = 0$, in which case it is E_r .

Proof By Theorem 2.3 we can find upper triangular maps $f; g: G \rightarrow G$, which represent the outer automorphisms corresponding to α and β . Thus we have that the following diagrams commute up to free homotopy.

$$\begin{array}{ccc} R_n & \longrightarrow & G \\ \downarrow & & \downarrow f \\ R_n & \longrightarrow & G \end{array} \quad \begin{array}{ccc} R_n & \longrightarrow & G \\ \downarrow & & \downarrow g \\ R_n & \longrightarrow & G \end{array}$$

Here α is a homotopy equivalence and R_n is the rose with n edges. By Proposition 3.12, we can assume that f and g satisfy the conclusions of that result. Next, we know that we can find paths $\gamma; \delta$ such that the following diagrams commute

$$\begin{array}{ccc} F_n & \longrightarrow & \pi_1(G; \nu) \\ \downarrow & & \downarrow f \\ F_n & \longrightarrow & \pi_1(G; \nu) \end{array} \quad \begin{array}{ccc} F_n & \longrightarrow & \pi_1(G; \nu) \\ \downarrow & & \downarrow g \\ F_n & \longrightarrow & \pi_1(G; \nu) \end{array}$$

Here, for a loop ρ , ρ is the inner automorphism induced by ρ , $\rho(\gamma) = \gamma \rho$.

As $\text{Fix } \alpha \setminus \text{Fix } \beta$ has rank at least two, we may apply Theorem 3.9 to find a path γ such that $f(\gamma) = \gamma$ and $g(\gamma) = \gamma$. Hence we get the following commuting

diagrams.

$$\begin{array}{ccc}
 {}_1(G; \nu) & \xrightarrow{-1} & {}_1(G; \nu) & & {}_1(G; \nu) & \xrightarrow{-1} & {}_1(G; \nu) \\
 \downarrow f & & \downarrow f & & \downarrow g & & \downarrow g \\
 {}_1(G; \nu) & & {}_1(G; \nu) & & {}_1(G; \nu) & & {}_1(G; \nu) \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 {}_1(G; \nu) & \xrightarrow{-1} & {}_1(G; \nu) & & {}_1(G; \nu) & \xrightarrow{-1} & {}_1(G; \nu)
 \end{array}$$

Thus we get a commuting diagram as required by the statement of this Theorem and, without loss of generality, we may also assume that there are no valence one vertices in G . If, for some r , there is no common INP of height r then we may apply Proposition 3.13 to deduce that the image of $Fix \setminus Fix$ in ${}_1(G; \nu)$ is a subgroup generated by loops, none of which cross E_r . This would imply that $Fix \setminus Fix$ is contained in a proper free factor, as G has no valence one vertices, and hence would be a contradiction. Thus there must be an INP at every height and we are done since we already know that f and g satisfy the conclusion of Proposition 3.12. \square

In order to prove that the fixed subgroup of any UPG subgroup is 1-auto-fixed, we need to invoke the following result.

Theorem 3.15 ([13], Corollary 4.2) *For any set $S \subseteq Aut(F_n)$, there exists a finite subset $S_0 \subseteq S$ such that $Fix(S) = Fix(S_0)$.*

Corollary 3.16 *Let $A \subseteq Aut(F_n)$ be a UPG subgroup such that $Fix A$ is contained in no proper free factor. Then there exists a $\geq 2 \subseteq Aut(F_n)$ such that $Fix A = Fix$. If the rank of $Fix A$ is at least 2, then we may choose $\geq 2 A$.*

Proof If $Fix A$ is cyclic, generated by w , then w cannot be a proper power and we can take to be the inner automorphism by w .

Otherwise, by Theorem 3.15, we note that it is sufficient to prove this Corollary for the case where A is generated by two elements, $;$. Apply Theorem 3.14 and, using the notation from that Theorem, consider the Upper triangular map $f g^k$ for some integer k . Clearly, $f g^k(E_r) = E_r \begin{smallmatrix} r_f + k:r_g \\ r \end{smallmatrix}$. If k is sufficiently large then $r_f + k:r_g$ is only equal to 0 if $r_f = r_g = 0$. For this value of k , a path is fixed by $f g^k$ if and only if it is fixed by both f and g . Hence $Fix \begin{smallmatrix} k \\ ; \end{smallmatrix} = Fix(h ; i)$. \square

Corollary 3.17 *Let $A \leq Aut F_n$ be a UPG subgroup. Then there exists a $\beta \in Aut F_n$ such that $Fix \beta = Fix A$*

Proof Let H be a free factor of F_n of smallest rank containing $Fix A$. Let $\beta \in Aut F_n$, then $\beta(H)$ is another free factor of F_n containing $Fix A$. Hence $H \setminus \beta(H)$ is a free factor of F_n and hence also a free factor of both H and $\beta(H)$. By minimality of the rank of H , $H \setminus \beta(H)$ must be equal to H and hence H is a free factor of $\beta(H)$. As the rank of H is equal to that of $\beta(H)$, $H = \beta(H)$ for all $\beta \in Aut F_n$.

Thus, we may look at the restriction of A to $Aut(H)$. By [3] Proposition 4.16, this is a UPG subgroup. Clearly, $Fix A$ is contained in no proper free factor of H and hence by Corollary 3.16, there exists a $\beta \in Aut(H)$ such that $Fix \beta = Fix A$.

As H is a free factor of F_n , we may find a basis x_1, \dots, x_n of F_n such that $H = \langle x_1, \dots, x_r \rangle$ for some r . Define $\beta \in Aut(F_n)$ by letting β agree with β on H and letting $\beta(x_j) = x_j^{-1}$ for $j > r$. Clearly, $Fix \beta = Fix A$, and we are done. □

4 The rank $n - 1$ case

In this section we describe the structure of fixed subgroups of exponential automorphisms where the fixed subgroup has rank one less than the ambient free group. In order to do this, we invoke the main Theorem of [12], but first a definition.

Definition 4.1 Let β be an automorphism of F and H a subgroup of F . H is called β -invariant if $\beta(H) = H$ setwise.

Lemma 4.2 *Let F_n be a free group with basis x_1, \dots, x_n and let H be the free factor $\langle x_1, \dots, x_{n-1} \rangle$. Suppose that for some $\beta \in Aut(F_n)$, H is β -invariant. Then $\beta(x_n) = u x_n^{-1} v$ for some $u, v \in H$. Moreover, if j_H has polynomial growth, then so does β .*

Proof As β is an automorphism, (x_1, \dots, x_n) is a basis for F_n . By applying Nielsen moves only on H we may deduce that $(x_1, \dots, x_{n-1}, \beta(x_n))$ is also a basis for F_n . (Alternatively, one can extend j_H to an automorphism, β^0 of F_n by letting $\beta^0(x_n) = x_n$. The image of (x_1, \dots, x_n) under the automorphism $\beta^{0^{-1}}$ shows that $(x_1, \dots, x_{n-1}, \beta(x_n))$ is a basis.)

Now we write $(x_n) = uvw$ where this product is reduced as written, $u, v \in H$ and w is a word whose first and last letters are x_n^{-1} . Clearly, the set x_1, \dots, x_{n-1}, w is a basis. Moreover it is a Nielsen reduced basis (see [10]) and hence $w = x_n^{-1}$. This proves the first claim.

To prove the second claim we note that if j_H has polynomial growth then $j^{-k}(g)j = jgjA^k$ for all $g \in H$ and some constants A, d . Hence,

$$j^{-k}(x_n)j = \prod_{i=0}^{k-1} j^{-i}(u)j + \prod_{i=0}^{k-1} j^{-i}(v)j + 1 \\ (juj + jvj + 1) \sum_{i=0}^{k-1} Ai^d \\ (juj + jvj + 1)Ak^{d+1};$$

from which it follows easily that $j^{-k}(x_n)j$ also has polynomial growth (where the degree of the polynomial is at most one higher). \square

The following result gives a description of 1-auto-fixed subgroups which will be particularly useful in our situation.

Theorem 4.3 [12] *Let F be a non-trivial finitely generated free group and let $\phi \in \text{Aut}(F_n)$ with $\text{Fix } \phi \neq 1$. Then, there exist integers $r \geq 1$, $s \geq 0$, ϕ -invariant non-trivial subgroups $K_1, \dots, K_r \leq F_n$, primitive elements $y_1, \dots, y_s \in F_n$, a subgroup $L \leq F_n$, and elements $1 \neq h_j^0 \in H_j = K_1 \cup \dots \cup K_r \cup \langle y_1, \dots, y_j \rangle$, $j = 0, \dots, s-1$, such that*

$$F_n = K_1 \cup \dots \cup K_r \cup \langle y_1, \dots, y_s \rangle \cup L$$

and $y_j = y_j h_{j-1}^0$ for $j = 1, \dots, s$; moreover,

$$\text{Fix } \phi = \langle h w_1, \dots, w_r; y_1 h_0 y_1^{-1}, \dots, y_s h_{s-1} y_s^{-1} \rangle$$

for some non-proper powers $1 \neq w_i \in K_i$ and $1 \neq h_j \in H_j$ such that $h_j = h_j^0 h_j h_j^{0-1}$, $i = 1, \dots, r$, $j = 0, \dots, s-1$. \square

Proposition 4.4 [5] *Let $\phi \in \text{Aut}(F_n)$ and suppose that $\text{rank}(\text{Fix } \phi) = n$. Then ϕ is UPG.*

Proof This follows directly from [5], although it is not stated in these terms. It can also be proven using Theorem 4.3, since the hypothesis guarantees that L is trivial and each K_i is cyclic. Since it is clear that H_j is ϕ -invariant, repeated applications of Lemma 4.2 show that ϕ has polynomial growth. We can then deduce that ϕ is UPG by inspection of the basis given in Theorem 4.3. \square

Proposition 4.5 Let $\alpha \in \text{Aut } F_n$ be an automorphism of exponential growth and suppose that $\text{rank}(\text{Fix } \alpha) = n - 1$. Then there exists a basis $x; y; a_1; \dots; a_{n-2}$ of F_n such that

- (1) Each free factor, $A_i = \langle hx; y; a_1; \dots; a_i \rangle$, is α -invariant. In particular, $\langle hx; y \rangle$ is α -invariant and $j_{hx; y}$ has exponential growth.
- (2) $a_i = a_i w_i$ where $w_i \in \langle hx; y; a_1; \dots; a_{i-1} \rangle$.
- (3) $\text{Fix } \alpha = \langle hxyx^{-1}y^{-1}; y_1; \dots; y_{n-2} \rangle$ where each y_i is equal to either a_i or $a_i g_i a_i^{-1}$ for some $g_i \in \langle hx; y; a_1; \dots; a_{i-1} \rangle$.

Proof We apply Theorem 4.3. First note that

$$F_n = K_1 \ast \dots \ast K_r \ast \langle hy_1; \dots; y_s \rangle \ast L = H_s \ast L$$

and that H_s is α -invariant. Moreover, $n - 1 = \text{rank}(\text{Fix } \alpha) = r + s + \text{rank}(L)$.

Hence if L is not trivial, then $n - 1 = \text{rank}(\text{Fix } \alpha) + \text{rank}(L) > n - 1$. Thus $\text{rank}(\text{Fix } \alpha) = s$ and $\text{rank}(L) = 1$. Thus, by Lemma 4.4, j_{H_s} has polynomial growth and we deduce that α has polynomial growth by Lemma 4.2. This is a contradiction as we are assuming that α has exponential growth, by hypothesis. Hence $L = 1$.

Since $r + s = n - 1$ and $n = \text{rank}(H_s) = s + \sum_{i=1}^r \text{rank}(K_i)$ it is easy to see that all but one of the K_i is cyclic and that this exception must have rank 2. Without loss of generality, $\text{rank}(K_1) = 2$ and every other K_i is cyclic. Let $x; y$ be a basis for K_1 and extend this to a basis $x; y; a_1; \dots; a_{n-2}$ where $a_1; \dots; a_{r-1}$ are the generators of $K_2; \dots; K_r$ respectively and $a_r; \dots; a_{n-2}$ are equal to $y_1; \dots; y_s$ respectively.

By construction, $a_i = a_i w_i$ where $w_i \in \langle hx; y; a_1; \dots; a_{i-1} \rangle$. Moreover,

$$\text{Fix } \alpha = \langle hxyx^{-1}y^{-1}; hy_1; \dots; y_{n-2} \rangle$$

where each y_i is equal to a_i if $i < r$ or $a_i g_i a_i^{-1}$ for some $g_i \in \langle hx; y; a_1; \dots; a_{i-1} \rangle$ otherwise. It is clear from the construction that the free factors A_i are α -invariant, since we know that K_i and H_i are α -invariant.

Now if $j_{hx; y}$ is of polynomial growth, then repeated applications of Lemma 4.2 would show that α has polynomial growth. Therefore, $j_{hx; y}$ is of exponential growth and has fixed subgroup of rank 1. Since automorphisms of the free group of rank 2 are geometric, $j_{hx; y}$ is realised as a pseudo-Anosov automorphism of a once punctured torus. Thus we see that, up to a choice of basis, the fixed subgroup of $j_{hx; y}$ is $\langle [x; y] \rangle$. □

The following shows how information about the fixed subgroup, when it is large, puts restrictions on the automorphism.

Lemma 4.6 *Let ϕ be an automorphism with fixed subgroup as in Proposition 4.5. Then there exists a relative train track representative of ϕ whose only exponential stratum is the bottom stratum corresponding to (the conjugacy class of) $hx; yi$. Moreover, this representative is aperiodic (see [2] Definitions 3.1.7).*

Proof First as the smallest free factor containing $xyx^{-1}y^{-1}$ is $hx; yi$, this must be ϕ -invariant, as ϕ sends free factors to free factors. Now let $A_i = \langle hx; y; a_1; \dots; a_i \rangle$ for $0 \leq i \leq n - 2$.

We claim that A_i is ϕ -invariant for all i . We have just shown that this is true for A_0 and we argue by induction. Suppose the claim holds for A_i . If $y_{i+1} = a_{i+1}$, then there is nothing to prove. So assume that $y_{i+1} = a_{i+1}g_{i+1}a_{i+1}^{-1}$ which is fixed by ϕ . Note that $g_{i+1} \notin A_i$ and by induction so is $\phi(g_{i+1})$. Thus, $a_{i+1}^{-1} \phi(a_{i+1})$ is in the normaliser of A_i , which is equal to A_i as free factors are malnormal. Hence $\phi(a_{i+1}) = a_{i+1}u_{i+1}$ for some $u_{i+1} \notin A_i$. This proves the claim.

Now, by [2] Lemma 2.6.7, there is a relative train track representative of ϕ , f on G , such that G has f -invariant subgraphs $G_1 \cup G_2 \cup \dots \cup G_{n-1} = G$ so that each G_i is a connected subgraph whose fundamental group is equal to A_i , via the marking.

Note that the difference in ranks between A_{i+1} and A_i is exactly one, so that each $G_{i+1} - G_i$ is a level stratum, for $i > 1$. Note also that as G_1 has a rank 2 fundamental group, f_{G_1} must be of exponential growth, since otherwise would have polynomial growth. In particular, f_{G_1} must be irreducible and also aperiodic. Hence the subgraphs G_i give a complete stratification, where only the bottom stratum is exponential and corresponds to the conjugacy class of $hx; yi$. Since this is aperiodic, the whole relative train track is aperiodic. \square

Proposition 4.7 *Let $\phi; \psi \in \text{Aut } F_n$ such that ϕ satisfies the hypotheses of Proposition 4.5. If $\text{Fix } \phi^{-1} = \text{Fix } \psi$ then $(hx; yi)$ is a conjugate of $hx; yi$.*

Proof By Lemma 4.6, ϕ has an aperiodic relative train track representative with a unique exponential stratum at the bottom. Thus ϕ has a unique attracting lamination, λ_ϕ , (see [2], section 3), and since the bottom stratum of our relative train track corresponds to $hx; yi$, the attracting lamination of ϕ is carried by the conjugacy class of $hx; yi$. (We shall abuse notation slightly and

call λ an attracting lamination for ϕ when it is strictly speaking an attracting lamination for the outer automorphism determined by ϕ .)

Since we have only used Lemma 4.6 and the fixed subgroup, we also deduce that the conjugacy class of $(hx; yi)$ also carries the unique attracting lamination, L , of ϕ^{-1} .

However, by inspection, the conjugacy class of $(hx; yi)$ must also carry the lamination λ (), where ϕ is the outer automorphism determined by ϕ . However, λ () is an attracting lamination for ϕ^{-1} , since ϕ induces a homeomorphism on B and sends bi-recurrent lines to bi-recurrent lines (see [2], Definition 2.2.2 and Lemma 3.1.4).

In other words λ () = L and $(hx; yi)$ is conjugate to $hx; yi$. □

5 Auto-fixed subgroups of rank $n - 1$

We shall need to quote one more result before we prove that the intersection of 1-auto-fixed subgroups is 1-auto-fixed if the rank of the intersection is at least $n - 1$.

Theorem 5.1 ([14], Lemma 3.1) *Let $\phi; \psi \in 2 \text{Aut}(F_n)$. Then there exists a positive integer k such that $\text{Fix } \phi \setminus \text{Fix } \psi$ is a free factor of $\text{Fix } \phi^k$.*

Theorem 5.2 *Let $\phi; \psi \in 2 \text{Aut } F_n$ and suppose that the rank of $\text{Fix } \phi \setminus \text{Fix } \psi$ is $n - 1$. Then there exists a $\chi \in 2 \text{Aut } F_n$ such that $\text{Fix } \chi = \text{Fix } \phi \setminus \text{Fix } \psi$.*

Proof By Theorem 5.1 there exists an integer k such that $H = \text{Fix } \phi \setminus \text{Fix } \psi$ is a free factor of $\text{Fix } \phi^k$. Either $H = \text{Fix } \phi^k$ or $\text{rank}(\text{Fix } \phi^k) = n$. In the former case, we are done so we shall assume that $\text{Fix } \phi^k$ has rank n and so by Proposition 4.4 is UPG. Applying Theorem 5.1 again, there exists an integer m such that $H = \text{Fix } \phi^k \setminus \text{Fix } \psi$ is a free factor of $\text{Fix } (\phi^k)^m$. Thus, without loss of generality, we may assume that $\text{rank}(\text{Fix } \phi) = \text{rank}(\text{Fix } \psi) = n$. Note that by [7], as ϕ restricts to a finite order automorphism on $\text{Fix } \phi^k$, $\text{Fix } \psi$ is a free factor of $\text{Fix } \phi^k$. But in our case, $\text{rank}(\text{Fix } \psi) = n$ and by Theorem 1.2, $\text{rank}(\text{Fix } \phi^k) < n$. Hence $\text{Fix } \phi^k = \text{Fix } \psi$ for all $k \neq 0$. By the same argument, $\text{Fix } \phi^k = \text{Fix } \psi$ for all $k \neq 0$.

If $h; i$ is a UPG subgroup then we are done by Theorem 3.17. If every automorphism in $h; i$ has polynomial growth then, by [3] Proposition 3.5, $h; i$ has a finite index UPG subgroup. However, we would be done in that

case since the fixed subgroups of σ_i are unchanged by taking proper powers. Thus we may assume that there exists a σ_i of exponential growth. If $\text{Fix } \sigma_i = H$ then we are done.

Now we can write $\text{Fix } \sigma_i = K \cdot L$, where K is an algebraic extension of H (see [9] or [17]). But, as H is inert, $\text{rank}(H) = \text{rank}(K) = \text{rank}(\text{Fix } \sigma_i)$ and since σ_i has exponential growth, we know by Proposition 4.4, that $\text{rank}(\text{Fix } \sigma_i) < n$. Thus $\text{Fix } \sigma_i = K$ is an algebraic extension of H . However, there are only finitely many of these, again by [17], and since H is fixed by both σ_i and σ_j , these two automorphisms must permute the algebraic extensions of H . Thus $\text{Fix } \sigma_i$ is stabilised by some powers of σ_i and σ_j , which without loss we may assume to be 1. (Note, in fact by [3], σ_i must always stabilise $\text{Fix } \sigma_i$.)

Hence, $\text{Fix } \sigma_i^{-1} = \text{Fix } \sigma_i = \text{Fix } \sigma_i^{-1}$.

By Proposition 4.5, there is a rank 2 free factor L of F_n which is invariant under σ_i and such that the restriction of σ_i to L is of exponential growth. By Proposition 4.7, σ_j sends L to a conjugate of itself. By the same argument, σ_i also sends L to a conjugate. Let ρ_i, ρ_j be automorphisms in the same outer automorphism class as σ_i, σ_j respectively which each leave L invariant.

By Theorem 2.4, ρ_i, ρ_j each restrict to a UPG automorphism of L . Thus, up to a choice of basis, ρ_i induces an action of the abelianisation of L corresponding to the matrix $\begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix}$ for some integer n . With respect to this basis

the induced action of ρ_j will correspond to some matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$; for some integers, a, b, c, d . As ρ_j is also UPG, the trace of this last matrix must equal 2.

By Theorem 5.1, there exists a positive integer k such that H is a free factor of $\text{Fix } \sigma_i^k$. Either this automorphism has fixed subgroup exactly equal to H and we are done, or it has fixed subgroup of rank n . In the latter case, it will be UPG, by Proposition 4.4. We shall show that this leads to a contradiction.

Note, again by [3] Proposition 4.6, σ_i^k induces a UPG automorphism on L .

Hence the matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix} : \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix}^k$ has trace 2.

Evaluating this matrix we see that $\begin{pmatrix} a & akn + b \\ c & ckn + d \end{pmatrix}$ can only have trace 2 if either $n = 0$ or $c = 0$. Note that the latter case forces $a = d = 1$. Hence the image of $\langle \sigma_i, \sigma_j \rangle$ in $GL(2; \mathbb{Z})$, under the natural map, is a subgroup consisting of upper uni-triangular matrices. Thus, after choosing a basis x, y for L , j_L is

the automorphism which sends x to $g^{-1}xg$ and y to $g^{-1}yx^t g$ for some integer, t , and some $g \in \langle hx, yi$. This contradicts the fact that $\langle j_L \rangle$ has exponential growth. (Here we are using the well known fact that the kernel of the map from $Aut(F_2)$ to $GL(2; \mathbb{Z})$ consists of precisely the inner automorphisms.) This contradiction completes the proof. \square

Corollary 5.3 Any auto-fixed subgroup of F_3 is 1-auto-fixed.

Proof By Theorem 3.15, it is enough to show that the intersection of two 1-auto-fixed subgroups of F_3 is also 1-auto-fixed.

Let $H, K \leq Aut(F_3)$ and let $H = \text{Fix}(H) \setminus \text{Fix}(K)$. We need to show that $H = \text{Fix}(H)$ for some $K \leq Aut(F_3)$. By Theorem 1.2, $\text{rank}(H) \leq 3$. If $\text{rank}(H) = 3$ then the result follows by [14], Corollary 4.1. If $\text{rank}(H) = 2$ then the result follows by 5.2. If $\text{rank}(H) = 1$ then $H = \langle hgi \rangle$ and the inner automorphism that is conjugation by g will have fixed subgroup equal to H . Finally, if H is trivial then one can find automorphisms which have no fixed points. An automorphism which cyclically permutes a basis would be an example. \square
